The contents of this magazine have been approved by the World Agricultural Outlook Board, and the summory was released July 19, 1991. Price and quantity forecasts for crops are based on the July 11 World Agricultural Supply and Demand Estimates.

Materials may be reprinted without permission. Agricultural Outlook is printed monthly except for the January-February combined

Annual subscription: \$26 U.S., \$32.50 foreign (Includes Canada). Order from ERS-NASS, P.O. Box 1608. Rockville, MD 20849-1608. Or call, toll free, 1-800-999-6779 (8:30-5:00 E.T.). Make check payable to ERS-NASS.

Time to renew? Your subscription to Agricultural Outlook expires in the month and year shown on the top line of your address label. Renew by calling 1-800-999-6779.

The next issue of Agricultural Outlook (AO-178) is scheduled for mailing on September 6, 1991. If you do not receive AO-178 by September 25, call the managing editor at (202) 219-0494 (be sure to have your mailing label handy). The full text of AO-178 will also be distributed electronically: additional information on this is available at (202) 447-5505.

News of Hog Herd Expansion, Milk Inventory Management Study, Bank Reform, and Mexico's Economic Reforms

The pork industry is set for an expansion in production during the second half of 1991 and beyond. The June *Hogs and Pigs* report showed a much larger herd expansion than anticipated earlier by industry analysts. Hog prices are expected to drop from about \$55 per cwt in July to the mid-\$40's by yearend.

The cattle-on-feed inventory for June 1 was the largest on that date since 1973, pointing toward greater fed cattle marketings in the third and fourth quarters. Fed cattle prices are expected to decline in the second half of 1991 as beef production expands.

Second-quarter data strongly suggest that the recession ended sometime in April or May. Production rose during those months, and in May consumer spending posted its biggest gain so far this year. The second-quarter job decline was the smallest since the recession began. However, despite the upward tilt of recent economic indicators, the economy is still operating at low levels and unemployment remains relatively high.

Many analysts believe the economy is poised to recover in the second half of this year. Interest-sensitive sectors, especially residential housing and automobiles, are likely to rebound most dramatically. Inflation should remain moderate, barring any unanticipated rise in energy or food costs.

USDA's Milk Inventory Management Report has generated considerable interest on Capitol Hill and in the dairy and related industries. Under the 1990 farm bill, the Department was required to report to Congress on the merits of alternative milk inventory management programs. In its final report to Congress on June 14, USDA concluded that the current dairy program measures up well against other options studied.

The report evaluated the current dairy program as well as four general alternative programs, with the objective of avoiding large milk surpluses. The approach was to quantify the potential effects of each alternative on milk production, use, and prices, and compare them with baseline projections under current policies. Each of the four alternatives was found to have shortcomings.

Congress is considering several proposals that could radically restructure the U.S. banking system. Farmers and other rural residents have a significant stake in the final outcome of the reform debate. Commercial banks account for the largest share of credit to farmers (35 percent in 1990) and are the primary source of credit to rural nonfarm businesses.

Significant proposed changes to the bank deposit insurance system could seriously hinder small banks' ability to compete with large banks. One result could be a substantial reduction in the number of small independent banks, including those serving rural credit needs.

The government of Mexico is embarked on a course of unilateral economic reform, reversing the direction of inward-looking economic policy pursued most of this century and moving toward a more open economy based on free trade and competitive markets. The new policies appear to be improving the efficiency and performance of the Mexican economy.

The economic reforms are potentially significant for the U.S. because Mexico is the third-largest U.S. trade partner and a border country. The reform process, by generating healthy economic growth and encouraging foreign investment, is providing opportunities for increased trade between the two countries.

Industrial crops—those used as inputs in manufacturing—are receiving considerable attention from farmers, rural businesses, and policymakers as they look at ways to diversify U.S. agriculture. Kenaf and milkweed are two that have potential to become major fiber crops, providing income for farmers, jobs for rural communities, and products for a wide range of uses.

USDA's June plantings survey showed 75.9 million acres planted to corn in 1991, only slightly lower than the March forecast. A decline of as much as 1 million acres had been expected for corn as late-season planting delays favored increased soybean plantings. Some switching to soybeans did occur in rain-soaked areas, but was offset by increased corn acres in other states.

Prices for most fresh fruits are expected to be higher this summer than a year ago. Output is expected down for oranges, cherries, apricots, plums, and nectarines. In contrast, a larger peach crop is expected to reduce peach prices. A rebound in cane sugar output in Louisiana is among the factors contributing to an expected 4-percent increase in U.S. sugar production in 1991/92. U.S. consumption is likely to trend up 1.4 percent.

Livestock, Dairy & Poultry Overview

The pork industry is set for an expansion in production during the second half of 1991 and beyond. The June Hogs and Pigs report showed a much stronger herd expansion than anticipated earlier by industry analysts. Hog prices are expected to drop from about \$55 per cwt in July to the mid-\$40's by yearend.

The June cattle-on-feed inventory was the highest on this date since 1973, pointing toward greater fed cattle marketings in the third and fourth quarters. Fed cattle prices are expected to decline from a year earlier in the second half of 1991 as beef production expands.

Dairy prices are likely to strengthen in the second half of 1991 as increases in milk production contract from levels achieved during the first half. However, milk prices for the year are expected to be below 1990.

Hog Herd Larger Than Expected

The June 28 Hogs and Pigs report showed a much stronger herd expansion

than indicated in previous reports. Strong expansion was indicated for both the short- and long-terms. Total inventories were up 5 percent from a year earlier, breeding inventories were up 6 percent, and market hog inventories increased 4 percent. Farrowing intentions, up 7 percent from 2 years ago, indicate that during September-November, virtually all states will show strong growth in hog numbers.

Third- and fourth-quarter slaughter are both expected to increase over 6 percent to 21.6 million and 24.2 million head, given the recent inventory report. These increases, coupled with heavier average weights, are expected to lower fourth-quarter prices to the mid-\$40's per cwt.

Second-quarter slaughter pushed year-todate slaughter above a year earlier. Still, the slaughter rate took its seasonal latespring dip, lifting hog prices in mid-May to over \$55 per cwt from around \$50 in April. Second-quarter barrow and gift prices averaged \$53, up over \$2 from the first quarter but down 9 percent from a year earlier.

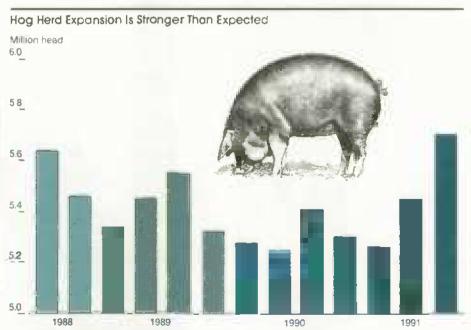

Retail pork prices, dropping since December, picked up nearly 2 cents per pound in May, mainly on pre-Memorial Day price strength. Quarter-to-quarter prices declined 2 cents in the second quarter from \$2.15 per pound. With little seasonal summer strength foreseen, and a substantial price drop expected this fall, pork prices for the year are likely to average 2 percent lower than a year earlier.

Monthly farm-to-retail price spreads have generally declined since the record highs of a year earlier. As farm prices decline in the fall, spreads are expected to widen late in the year and put average 1991 spreads 1 to 3 percent higher than \$1.25 a year earlier.

Fed Cattle Marketings To Move Up

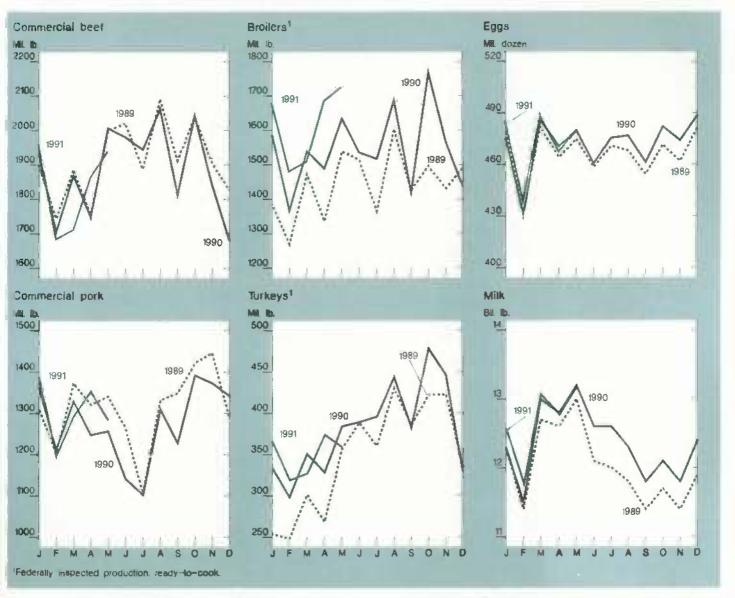

The June 1 Cattle On Feed report showed the fed cattle inventory up 9 percent from a year ago in the seven monthly reporting states, the largest inventory since 1973 on this date. Larger cattle-onfeed inventories point toward expanding fed cattle marketings in the third and fourth quarters.

Placements on feed during May were 8 percent above a year earlier but below the 1985-89 average. Marketings during

Hog and pig breeding herd inventory. Beginning of quarter,

Livestock & Product Output

May were off 5 percent from the year before, but more consistent with May's federally inspected steer and heifer slaughter than April's relatively high marketings.

Forage conditions on July 1 were the best since 1983 and are seen as a plus for beef cow operations. The July Crop Production report indicated pasture and range conditions in the 48 contiguous states were good to excellent in 29 states, poor to fair in 11 states, and very poor in Connecticut, Maine, Maryland, New Mexico, New York, Rhode Island, and West Virginia. In addition, Pennsylvania is undergoing a severe drought.

Beef cow slaughter is at a cyclical low, partly in response to ample forage supplies and favorable stocker and feeder cattle prices. This indicates that beef cow-calf operations are retaining cows. The July U.S. cattle inventory is scheduled for release on July 29.

Beef Cow Slaughter Down

Commercial cow slaughter this year is expected to be 5.9 million head, about the same as a year earlier. Dairy cow slaughter is forecast to remain above last year's 2.7 million head due to less favorable milk-to-feed price ratios this year. However, beef cow slaughter is ex-

pected to be below last year's 3.2 million head due to favorable returns and ample forage supplies.

First-quarter commercial cow slaughter was near 1.5 million head, 3 percent below a year earlier, and the lowest since 1980 for this period. First-quarter beef cow slaughter was off 8 percent and dairy cow slaughter up 2 percent from a year earlier. The lowest quarterly cow slaughter usually occurs during the spring, suggesting a further drop in the second quarter.

Retail Choice beef prices are expected to continue dropping in the coming months. Prices have eased 6 cents since the record \$2.97-per-pound high in April.

June's farm-to-retail spread widened to \$1.31 per pound, up 10 cents from April as fed steer prices dropped faster than retail prices. Fed steer prices have continued to drop from May's monthly average of \$78.47 per cwt, and have recently been trading in the low \$70's.

Broiler Output Growth Slows, Net Returns Drop

Fourth-quarter broiler production will likely be 4-5 percent greater than a year earlier, slowing from an 8-percent increase a year ago. Growth during the third quarter is likely expanding 6 percent from a year earlier, a faster growth rate than a year ago.

The expected slowdown reflects lower industry net returns during first-half 1991. First- and second-quarter net returns each averaged 6 cents a pound, compared with nearly 11 cents a year earlier. Third-quarter average net returns probably will be 6-7 cents, also below a year ago, reflecting continuing lower prices.

Average wholesale broiler prices in the third quarter are expected to average in the low-50's, about even with 52 cents per pound in the second quarter, but down 5 cents from a year earlier. Prices are expected to remain above cost this summer due to seasonal demand for chicken. Broiler prices are expected to average in the high 40's this fall.

A continuing high level of exports is providing some price support. Total U.S. broiler exports are estimated at 1.1 billion pounds in 1991, 6 percent below last year's record, as sales to the USSR, dependent on export credit guarantees this year, are down.

Retail prices for whole broilers in May averaged 88 cents a pound, almost 2 cents below a year earlier. Prices are expected to average in the high 80's in 1991, and remain below year-earlier levels through the second half due to competition from larger supplies of red meat.

Turkey Output Eases, Stocks Continue High

Fourth-quarter turkey output is expected to increase only 1 percent from a year earlier. Output this quarter is expected to be unchanged from a year ago. Second-quarter turkey production increased about 3 percent from a year earlier, well below the 9-percent growth in second-quarter 1990.

For 1991, production will be up only about 2 percent, the smallest annual increase since 1984. Slower growth reflects grower losses experienced from December through April.

Stocks continue to be record high, mainly due to last year's large production. Whole-bird stocks were up 27 percent, while other stocks were 7 percent below a year earlier due to increased processing use. On June 1, stocks totaled 448 million pounds, 10 percent above a year earlier. However, turkey stocks-to-use ratios are not abnormally large, and are not expected to generate large downward price movements.

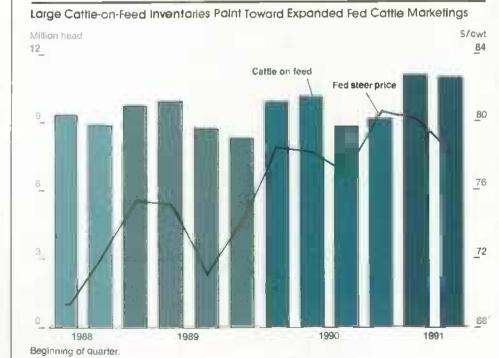

Fourth-quarter Eastern region wholesale hen prices are expected to strengthen

seasonally and average about the same as a year earlier. Third-quarter prices are supported by prospects for only moderate production growth in the second half of 1991, but are restrained by large stocks. Eastern region wholesale hen prices are expected to average 63-69 cents a pound this quarter, about the same as a year earlier.

Grower net returns improved in the second quarter to just above breakeven, helped by lower feed prices. Returns are expected to improve again during the third and fourth quarters and average slightly above 1990 for the year.

Egg Production Slows, Prices & Returns Lower

Based on producers' conservative approach to expansion, 1991 egg production is forecast at 5.69 billion dozen, fractionally larger than a year earlier. Table-egg production is expected to range from last year's level to 1 percent lower. The total laying flock size is expected to remain about the same, with the table-egg flock unchanged to slightly smaller.

m many about PDF Compression and OCR vielt our website

All growth is in the broiler-hatching egg flock, with a June 1 year-over-year increase of 7 percent. The egg-type hatching flock was 9 percent smaller.

The table-egg flock size indicates secondquarter production was unchanged from a year earlier to 1 percent lower. Production in the second half of 1991 is also expected to be about the same to 1 percent lower than a year earlier.

Wholesale prices are expected to remain relatively strong through 1991, but below a year earlier. Net returns will likely remain positive, but lower than last year. An average New York price of 76-79 cents per dozen is expected for the year, below the record 82 cents of the past 2 years.

Fourth-quarter prices are expected to rise to 75-81 cents, up from 73-79 cents in the third quarter. Retail prices in 1991 are forecast to average in the mid-90's, several cents below the high levels of about \$1.00 during 1989 and 1990. The first-quarter average retail price of \$1.05 was likely the peak for the year.

Dairy Prices May Rise In Second-Half 1991

In light of recent market tightness, dairy prices are likely to be stronger during the second half of 1991 than previously expected. If milk production continues to weaken and the economy bounces back as expected, then dairy prices are forecast to rise during the last 6 months of the year.

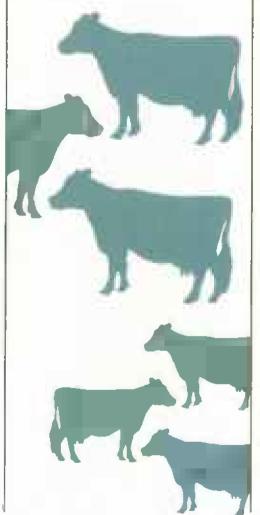

Seasonal increases in wholesale dairy product prices began in early May due to shrinking milk supplies and tightening cheese markets. By early June, wholesale cheese, butter, and nonfat dry milk prices were above price support purchase levels for the first time since last October.

Although U.S. milk production during the first half of 1991 was up 1 percent from a year earlier, production increases ended in May in response to substantially lower farm milk prices. In May and June, U.S. output was virtually unchanged from a year earlier.

Output during the second half of 1991 is forecast unchanged from a year earlier. Milk production in 1991, however, is forecast to reach a new record of 149 billion pounds.

Milk prices received by farmers averaged \$11.40 per cwt in June, \$2.40 below a year earlier. Recent forecasts for second-half 1991 milk prices are relatively higher than those made earlier this spring because milk output has slumped and wholesale dairy product prices are up. For the year, milk prices are expected to average 13-15 percent below a year earlier.

For further information, contact: Richard Stillman, coordinator; John Ginzel, cattle; Felix Spinelli, hogs; Lee Christensen, Agnes Perez, and Larry Witucki, poultry; Jim Miller and Sara Short, dairy. All are at (202) 219-1285.

Field Crops Overview

Weather conditions and changes in farm programs have had considerable impact on farmers' planting decisions. In many rain-drenched areas, acreage shifted from corn to soybeans. Plantings of other oilseeds are also up, and favorable weather increased spring wheat plantings,

Despite drought in California and heavy Delta rains, cotton acreage is up. Increased world cotton production should take the pressure off tight global supplies, but world trade is expected to remain at last year's level.

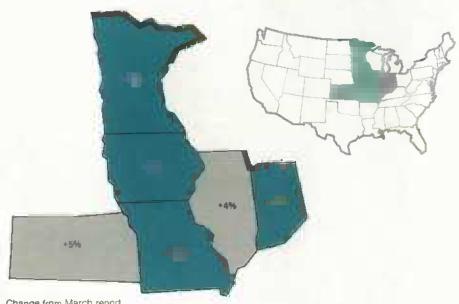

World rice production will drop in 1991 largely because of reduced output in the two leading producer countries, China and India. Little change is projected for U.S. output.

Corn Acreage Higher Than Expected

USDA's June plantings survey showed 75.9 million acres planted to corn in 1991. While the report showed area only slightly lower than the March planting intentions, the estimate came as somewhat of a surprise to industry analysts. A decline of as much as 1 million acres from the March forecast had been expected for corn as late-season planting delays were thought to have promoted more soybean plantings at the expense of corn. Some switching to soybeans did occur, but was offset by increased corn acres in other states.

Not unexpectedly, rain-soaked Iowa, with only 12.2 million acres of corn planted, registered the largest state decline (800,000 acres or 6 percent) from the March report. The decrease in corn acreage was offset by gains in soybean plantings. Other states showing declines in corn area include Indiana, Minnesota, and Missouri. Both Illinois and Nebraska posted 400,000-acre gains.

Weather Lowers Corn Planting Decisions in Some Major Producing States

Change from March report.

The bearish acreage report for corn was coupled with a bearish weather forecast for July which predicted warm temperatures and adequate precipitation across much of the Corn Belt. July and August weather are critical for com. Hot, dry conditions during those months can significantly reduce pollination and cut yields dramatically.

On the heels of the acreage and weather reports, futures contract prices at the Chicago Board of Trade fell to contract lows. However, as of July 14, the portion of the com crop rated good to excellent-66 percent-was lagging last year's 75 percent. During the first 2 weeks of July, corn crop conditions fell as temperatures rose in Illinois, Indiana, Iowa, Nebraska, and Ohio.

On June 27, USDA released its Grain Stocks report, indicating June 1 corn stocks of 2.99 billion bushels, up 5 percent from a year earlier. Although corn usage is expected to remain strong through the remainder of the crop year, the stocks level indicates somewhat lower feed and residual usage than had been expected by some analysts.

Wheat Plantings Still Strong

Wheat area planted for 1991 is estimated at 70 million acres, down 9 percent from a year earlier, but up 1 million acres from March intentions. Farmers intend to harvest 58 million acres of wheat for grain, a 16-percent drop from 1990. Winter wheat area harvested in Oklahoma and Colorado declined from the early June estimate, reportedly because of increased having and grazing of wheat. In Washington, more acres of winter wheat were reseeded to spring wheat because of last December's freeze.

Total spring wheat plantings were boosted by increased area in North Dakota. Spring wheat area intended for harvest in that state stands at an unusually high 98 percent of planted area. June crop conditions in the Northern Plains were the best in many years.

U.S. Rice Supplies To Expand

U.S. rice output for 1991 is forecast at 157.5 million cwt, slightly above the previous 2 years. Beginning inventories for

rice are forecast about the same as a year earlier. Including a modest increase in imports, rice supplies will grow more than 3 million cwt this year. Total use during 1991 is expected to grow, based largely on the strength of the domestic market.

Forecast rice plantings in 1991 are marginally down from a year earlier. Harvested area, however, is forecast up from 1990's difficult harvest, with Arkansas accounting for most of the gain.

World rice production in 1991/92 is projected to fall 1 percent from the 1990/91 record, due mainly to reduced output by the two largest producers. China and India. Both countries had record yields and harvests in 1990/91.

China's crop is projected down 3 percent. Although the government of China is encouraging farmers to maintain plantings, large supplies and low prices are expected to lead to a slight reduction in China's rice area. The monsoon in India is off to a good start, except in the northwest, where about 25 percent of the crop is grown. While area is projected to be virtually unchanged, lower fertilizer use and lower yields are projected to cut production by 3 percent.

Global rice consumption is expected to slip, but to remain near the 1990/91 record, and a slight drop in global ending stocks is anticipated. A small pickup in world trade is projected, due to lower production and projected increases in exportable supplies.

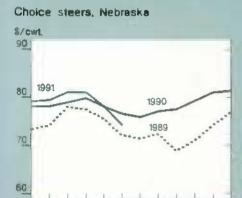

Thailand is projected to harvest a larger crop than a year earlier, and is expected to register the largest export gain. Exports by Pakistan are projected to show no change, while exports by Vietnam and China are likely to decline. U.S. rice exports and market share are each projected to decline in 1991/92 in the face of tight supplies, relatively high prices, and strong competition.

Oilseed Plantings To Increase

In the June plantings survey, U.S. farmers indicated they would plant

Commodity Market Prices

Agricultural Economy

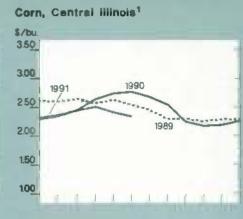

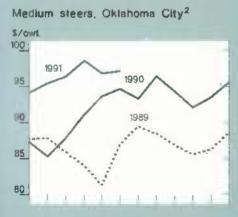

Broilers, 12-city average

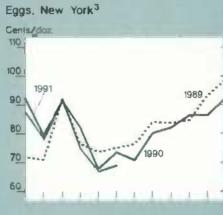

Centa/b

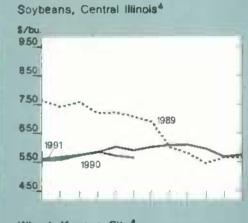

1990

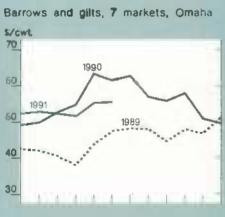

1990

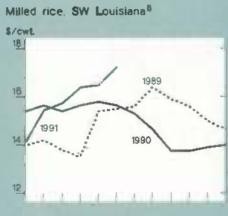

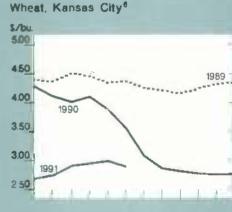

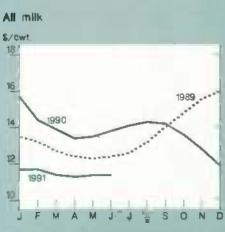

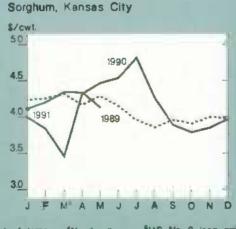

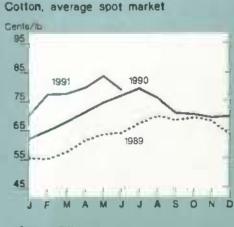

¹No. 2 yellow. ²600-700 lbs. medium no. 2. ³Grade A large. ⁴No. 1 yellow. ⁵U.Ş. No. 2, long-grain. ⁶No. 1 HRW.

significantly more oilseeds than intended earlier this spring. Rain-delayed plantings of corn throughout the Northwest Corn Belt and Delta regions, together with favorable growing conditions in the Northern Plains and more flexible commodity programs, contributed to the shift toward oilseeds.

Overall, farmers planted or intend to plant 62.7 million acres of soybeans, sunflowers, and flaxseed, up 2.9 million acres from their March intentions and 4.5 percent above a year earlier.

Soybeans led the increase in oilseed plantings with an estimated 59.8 million acres, up nearly 2.7 million acres from March and 2 million acres above last year. The significant increase in bean acreage reflects farmers' response to added flexibility in commodity programs and to heavy spring rains that delayed corn and cotton plantings.

Northern Plains producers are also reacting to abundant spring rains that have generated optimism for this year's yield prospects. The largest soybean acreage increases were noted in Iowa (800,000), Minnesota (500,000), and Missouri (500,000).

Acreage planted to sunflowers and flaxseed also gained over earlier intentions. Sunflower acreage is now estimated at 2.6 million, up 11 percent from March intentions and 36 percent above last year. While flaxseed plantings are also estimated up from a year earlier, low earlyseason prices have discouraged some plantings, and acreage is down from the March report.

This year's increase in minor oilseed acreage reflects farmers' responses to new commodity program provisions that combine planting flexibility with price supports. Producers in the Northern Plains are also benefiting from some of the best growing conditions in years, decreasing yield risks and bankers' apprehension.

Record World Oilseed Output Forecast

Global output of oilseeds in 1991/92 is projected at 223.8 million tons, up 6.1 million above the 1990/91 record, reflecting gains in rapeseed, cottonseed, peanut, and soybean production. Declines are expected for sunflowerseed, flaxseed, and copra.

Large rapeseed crops are projected for the EC, China, and Canada, all the result of increased 1991/92 plantings. The rebounding U.S. peanut crop is the main reason for higher world production, while India accounts for most of the gain in foreign output. Most of the anticipated increase in world cottonseed production is dependent on China. Global production of soybeans is forecast to rise 3 percent in 1991/92 to 107 million tons. Foreign soybean output is projected up 21 million tons, also up 3 percent, led by gains in Brazil. Another large crop is likely in China, although production is projected up only 1 percent from last year's abundant output.

Soybean prospects for the major competing suppliers, Brazil and Argentina, are uncertain this early in the year. Both are now winding up 1990/91 harvests, and planting of new crops is still months away. Changing policies and tough economic conditions cloud the outlook for both countries.

In Brazil, output is projected to rise 2 million tons because of improved yields after poor weather in critical areas pulled down 1990/91 production. Limited government resources may restrict credit

for soybean growers and hold down potential area gains.

In Argentina, soybean production is projected to decline 250,000 tons from the record 1990/91 outturn, as yields are likely to return to trend following unusually favorable growing conditions in 1990/91. Area is expected to rise to 5 million hectares.

World soybean trade in 1991/92 is projected to rise 6 percent to 26.6 million tons, while soybean meal trade will likely slip 1 percent to 25.8 million tons. Imports by the Soviet Union will again be constrained by limited availability of foreign exchange. The U.S. offer of credit is expected to favor the U.S. over competing South American exporters in the Soviet market.

U.S. soybean exports are projected at 17.4 million tons, pointing to a market share of 65 percent. Foreign exports are forecast at 9.2 million tons. U.S. soybean meal exports are projected at 5 million tons, and foreign shipments 20.8 million.

World vegetable oil inventories are forecast to rise in 1991/92. Supplies of major oils are expected to grow more rapidly than the 2-percent gain forecast for global use. Soybean and palm oil are likely to account for most of the inventory gain, with soybean oil stocks in the U.S. projected to reach near-record levels of more than 2 billion pounds.

Larger Acreage To Boost U.S. Cotton Production

Despite setbacks in California and the Delta, U.S. cotton producers expect to plant over 14 million acres in 1991, according to USDA's June Acreage report. Spurred by relatively strong cotton prices, producers have continued to plant cotton beyond yield-optimal planting dates in many areas.

In California's pivotal San Joaquin Valley, an exceptionally cool April-to-mid-May period has probably hindered early crop development. In the Mississippi Delta region, April was the wettest on record in many areas, with rainfall totaling 30 inches or more. Some acreage could not be planted and much was planted late.

Based on plantings reported in the June survey, U.S. cotton production in 1991 could exceed 16 million bales. Mill use will likely remain steady near 1990 levels, while U.S. cotton exports will likely fall, due to larger foreign outturn.

U.S. ending stocks in 1991/92 are expected to total 3.0 million bales, and stocks-to-use is forecast at 19 percent, up from a year earlier but well below the 1990 farm bill target of 30 percent.

World Cotton Outturn To Reach Record

The current tight world supply of cotton should ease somewhat in 1991/92 due to a projected 4-percent increase in world production to a record 90.3 million bales. Foreign production is projected to rise 3 million bales to 74.1 million, just 2 million below the 1984/85 record.

Most of the foreign production increase is expected in China, but this will hinge on the size of its increase in cotton area. Prices for some competing crops in China, such as corn, have been depressed by large 1990/91 supplies in some areas. In addition, record output is projected for Pakistan, and India's crop is forecast up 7 percent—the second largest ever.

World consumption is projected to rise nearly 1,7 million bales in 1991/92, also a record. Production gains are expected to outstrip consumption substantially, leading to a small increase in ending stocks. Most of the prospective consumption gains are anticipated in the major producing countries.

World cotton trade is projected to remain stable at 23.5 million bales in 1991/92. U.S. exports are expected to fall 11 percent to 7 million bales in the face of increased foreign competition. The U.S. market share is projected to decline to a more normal 29.7 percent from 1990's 34-percent level.

Foreign cotton exports are projected to rise 8 percent. A critical element of the trade outlook will be how the Soviet Union resolves the key issue of cotton sales and retention of foreign exchange by its producing republics. In 1990/91, the republic of Uzbekistan accumulated large stocks which may hit the world market in 1991/92. [Jim Cole (202) 219-0840 and Pete Riley (202) 219-0825]

Specialty Crops Overview

Most fresh-fruit prices in the U.S. are likely to be up this summer from a year ago. Output is expected down for oranges, cherries, apricots, grapes, pears, plums, and nectarines. Apple and freestone peach production is expected to be higher.

Acreage planted with fall potatoes rose 2 percent from a year earlier. Grower prices are likely to be lower than the last two seasons when moderate-size crops and strong gains in demand kept prices above trend.

A rebound in cane sugar output in Louisiana is among the factors behind the 4-percent increase expected in U.S. sugar production in 1991/92. U.S. consumption is likely to trend up 1.4 percent.

Higher Fruit Prices In 1991

Most fresh fruit prices are expected to be higher this summer than a year ago because of reduced output. Peach prices, however, are expected to decline due to a larger crop.

The U.S. freestone peach crop is forecast up 33 percent in 1991 compared with a year carlier and up 18 percent from 2 years ago. The adverse impact of last December's freeze on expected peach production in Western states is more than offset by forecast bumper crops in the Eastern states. Grower prices for fresh peaches early in the season were running slightly ahead of a year earlier because of good quality and strong demand. However, they are expected to slip a little as the season progresses.

Smaller orange supplies than a year earlier may be helping to put a floor under peach prices. Much of California's orange production was destroyed by abnormally cold weather last December, contributing to the strong demand for other fresh fruits this summer. The impact on demand for noncitrus fruits is expected to last into next season.

Except for freestone peaches and dried prunes, overall stone fruit production is expected to be lower in 1991. Sharp declines in sweet cherry output are likely in Washington, Oregon, Utah, and Idaho. The cold wave that swept the Western states in late December is expected to push total Western production 24 percent lower than last year.

California growers are likely to see smaller apricot, plum, and nectarine crops—these also were damaged by the December freeze. Apricot production is expected to be 22 percent lower than last year, while plum output is forecast down 5 percent. Nectarine output is forecast to dip slightly. Dried prune production in California is expected to be 22 percent above a year earlier.

A 3-percent increase in apple production is expected. Output is forecast higher in the Eastern and Central states, where cold weather reduced the 1990 crop. Winter damage and frost also are factors in the 7-percent-lower 1991 forecast for the Western states.

California grape output is expected to be 2 percent lower than in 1990, reduced by high temperatures throughout the state. Production is forecast 2 percent lower for the raisin type, virtually unchanged for the wine type, and down 7 percent for the table type.

California's walnut production is forecast at 240,000 tons (in-shell basis) a 6-percent increase over 1990/91, and the second-largest crop on record. California's almond crop is forecast at 460 million pounds (shelled basis), 30 percent below last season's record harvest.

Trade sources indicate that pistachio production in California will be about 45 million pounds, much smaller than last year's record 118 million. Early-season industry reports on the pecan crop indicate production similar to 1988, when 308 million pounds (in-shell basis) were produced, much higher than last season's small crop of 205 million. Pistachios, and to a lesser extent pecans, are alternate-bearing crops, with a large crop usually followed by an off year in which production is much lower.

Potato Acreage Up

In 1991, growers planted 1 percent more acres with potatoes than a year earlier. Acreage for fail harvest jumped to 1.19 million, up 2 percent from last season and 8 percent above 1989. The largest gains are in Washington, where yields typically average the highest in the country.

Growers in Washington are expected to harvest 9 percent more fall acreage than last year. Producers in the Western potato states increased planted area by 2 percent. Western states' acreage is heavily concentrated in russet varieties for processing and for fresh baking use.

Producers in the Central states increased planted area for fall harvest by 2 percent. The biggest gain was in North Dakota, where area is up 5,000 acres.

Eastern farmers fractionally reduced planted area for fall harvest. Eastern production is dominated by the round white varieties typically used for processing into chips or for the fresh market.

Summer potato production is estimated at 22.8 million cwt, down slightly from 1990. Combined output for the winter, spring, and summer seasons is 45.6 million cwt.

Although the average grower price for potatoes rose during May because of a short spring crop, prices remained below a year earlier. Average prices for the past two seasons have been above trend, partly as a result of moderate-size crops and partly due to expanding demand for potatoes.

If yields from the fall crop match the average for the 3 years prior to 1988—310 cwt per planted acre—fall output could tally 365 million cwt and the total output for all four seasons would approach 410 million. Total output was 393 million cwt in 1990 and 370 million in 1989.

Losses due to drought in the Red River Valley during the 1988, 1989, and 1990 seasons pulled down the average U.S. yield. This season, moisture conditions in the Red River Valley were favorable as of mid-July, and potato fields reportedly looked good.

If U.S. production reaches 410 million cwt, prices likely will retreat from the 1990/91 marketing season levels. As a rule of thumb, the season-average grower price declines about 4 percent for each 1-percent increase in production. However, the size of fresh and processed

potato stocks at the beginning of the fall season, and changes in demand, can cause prices to deviate from the 4-percent rule of thumb.

Sugar Supplies To Rise in 1991/92

U.S. domestic sugar supplies are forecast to increase by 0.8 million short tons, raw value, in 1991/92 (October-September). A 500,000-ton increase in carryover stocks and higher production are contributing factors.

Early prospects point to record or nearrecord U.S. sugar production in 1991/92. Cane sugar output will show an especially large gain. Growing conditions in Florida so far this season reportedly have been better than usual. In addition, Louisiana appears on the verge of a dramatic recovery from the abnormally small 1990/91 crop, despite excessive rains this spring.

Beet sugar production also is likely to rise from last season although planted acreage is about the same as a year earlier. No major problems have been reported from the sugarbeet areas that would alter the forecast for higher yields in 1991/92.

U.S. sugar consumption in 1991/92 will be 1.4 percent higher as deliveries for domestic food and beverage use continuc trending up. Consumption in 1990/91 is likely to total 8.75 million tons, raw value, 2.8 percent higher than a year earlier.

Cigarette Exports Lift U.S. Tobacco Prices

Grower prices for U.S. tobacco are expected to increase in 1991/92 because of smaller domestic supplies and higher price supports. The decline in supplies will result from lower carryover stocks. An expected 3-percent increase in disappearance of U.S. tobacco for cigarette production in 1990/91 will absorb stocks. Strong export demand is driving the growth in cigarette production.

Domestic leaf disappearance during 1990/91 was higher for the second consecutive season despite declining U.S. cigarette consumption. Rising exports have been behind the growth in total cigarette sales in recent years. However, continuing declines in domestic consumption likely will overcome the growth in exports and reduce domestic leaf use later in the 1990's.

Tobacco stocks carried over to the new marketing year (beginning July 1 for fluecured and October 1 for burley and other varieties) likely will decline 5 percent from last year's 2.34 billion pounds.

Leaf exports for 1990/91 will probably decline slightly from the season before (final figures are not yet reported). But manufacturers in a number of countries are shifting to American blend cigarettes, which is expected to generate a small rise in leaf exports in 1991/92.

Production prospects for 1991/92 are similar to the previous season's. If acreage is near producers' planting intentions and yields are normal, an estimated 1.6 billion pounds of tobacco will be produced, about the same as a year earlier.

Flue-cured output would be expected at around 900 million pounds, while burley would account for 660 million. Marketing quota constraints will limit flue-cured sales to about 900 million and burley to 650 million. [Glenn Zepp (202) 219-0888]

Commodity Spotlight

Kenaf & Milkweed: New Fiber Crops

armers, rural businesses, and policymakers are looking to alternative crops to diversify U.S. agriculture. Industrial crops—those used as inputs in manufacturing—are receiving some of this attention. Kenaf and milkweed are two that have potential to become major fiber crops, providing additional income for farmers, jobs for rural communities, and products for a wide range of uses.

Kenaf Acreage Contracted For Commercial Use

Kenaf (pictured above) is a herbaceous annual grown in many tropical and subtropical countries as a substitute for jute in making twine, rope, and other cordage products.

Plants range in height from 12 to 18 feet. Leaves are either palmate or whole, depending upon the variety. Stems consist of an outer bark composed of bast (woody) fibers and an inner core containing shorter fibers. The longer bast fibers make up about 30 to 40 percent of the stem, on a dry-weight basis, and the shorter core fibers make up the remainder.

Until recently, kenaf was grown in the U.S. only for research purposes, primarily in Texas, Mississippi, and Oklahoma. This spring, however, a commercial firm—Natural Fibers of Louisiana, Inc.—contracted with farmers to plant 1,000 acres of kenaf in Louisiana.

Standard farm equipment can be used for planting and cultivation. Harvesting occurs during the fall, and the method varies depending on location and intended use of the fiber. The acreage in Louisiana will be harvested with a sugarcane harvester, and the stems will be field dried and stored on the farm for periodic retrieval by the processor.

In Texas, a prototype harvester has been developed that cuts the stems and lays them in rows. After 10 to 14 days of field drying, the stems will be gathered and shredded to be used for paper pulp.

In Mississippi, the weather at harvest time is a major variable. Field drying is not an option because heavy rains can coincide with the harvest. Researchers expect that a desiccant, or drying agent, will need to be applied before harvest.

Natural Fibers of Louisiana, Inc. is building a fiber separation plant near Jeanerette, Louisiana, to process the kenaf stems into bast and core fibers. The bast fibers have many uses, including fiberboard, molded car parts, acoustic tiles, carpet padding, burlap, and fiber mats. The primary use of the core fibers will be for poultry litter.

Kenaf To Yield Improved Newsprint

A kenaf-based newsprint mill is planned for south Texas, to be located in the Rio Grande Valley near Raymondville. Construction is expected to begin later this year and be completed in 1992.

Farmers in surrounding counties will grow the 4,500 acres of kenaf needed to keep the mill running. Yields are

expected to be about 6-8 tons per acre. When operational, the mill will produce 30,000 tons of newsprint annually.

Kenaf offers several advantages over conventional newsprint. It has excellent strength, better ink adherence (requiring less ink), and reduced ink runoff, and it provides sharper photo reproduction. Kenaf also requires less energy for pulping and brightens more easily than wood chips. Furthermore, it can be blended with recycled newsprint to improve paper quality.

Kenaf also has potential as forage for cattle and sheep. Crude protein content is between 15 and 22 percent depending on the part of the plant used, with leaves higher in protein than stems. If the crop is grown for forage only, farmers can get two cuttings per growing season. If the stems are harvested for fiber, the upper 2 to 3 feet of the plants can be ground and used as a feed ingredient.

Low Yields Slow Milkweed Development

Two milkweed species, common and showy milkweed, are being grown in Nebraska for their floss. The floss, the plants' natural medium of seed dispersal, interests entrepreneurs and scientists for use in insulated clothing, nonwoven textiles, and tissue paper.

During World War II, milkweed floss was substituted for kapok in life jackets. In the 1970's, the Department of Energy, Standard Oil of Ohio, and other establishments conducted research on the milky latex of the plant as an energy source. When research was discontinued, an individual at Standard Oil saw greater market potential in the floss than the latex. As a result, Natural Fibers Corporation (no connection with Natural Fibers of Louisiana, Inc.) was formed to study and commercialize milkweed floss.

Milkweed has been produced in Nebraska for 4 years as part of the company's experiments, with approximately 160 acres being grown this year. The plant is a perennial; commercial stands should last 5 to 10 years. About 20 inches of water are needed annually to maintain plant populations and promote pod formation.

Low yield is the major factor holding back the development of milkweed as a commercial crop. Yields in research plots during the last 5 years have averaged about 400 pounds of floss per acre, but those results have not been duplicated under field conditions.

Weeds, such as nightshade and foxtail, and diseases, such as black leaf spot and bacterial blight, have been major problems. In 1990, the average commercial yield was only 6 pounds of floss per acre, but that was double the 1989 average. The best field produced 28 pounds per acre, almost triple the highest yield in 1989. Half the fields in 1990 had no yield at all.

The University of Nebraska has modified a self-propelled corn picker to harvest milkweed pods. The pods are harvested in August while they are green, to prevent floss degradation and loss. After harvest, the pods are cracked open in a "conditioner" to expose the floss for drying.

A two-step drying process reduces moisture from about 80 percent to about 10 percent. After drying, the floss is mechanically separated from pod shells, seeds, and other debris. About 500 pods are required to produce a pound of floss.

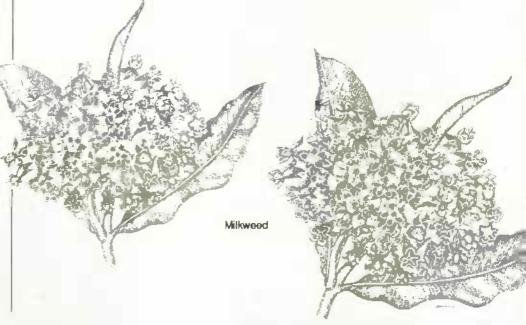

Milkweed's Potential As Fiber & Filler

Milkweed floss is a hollow fiber of about the same density as high-quality goose or duck down. Tests conducted at Kansas State University show that the floss is a better insulator than goose or duck down. The fibers are covered with a natural wax, making them water resistant. Also, because the fibers are made of cellulose, they should not produce allergic reactions. In laboratory and consumer tests, allergic responses have been negligible.

These characteristics, combined with the light weight of the floss, make it a good candidate for filter in comforters, sleeping bags, and insulated clothing. Natural Fibers Corporation is manufacturing comforters filled with a mixture of milkweed floss and goose down.

Textile experts at the University of Nebraska are examining the use of milkweed floss in nonwoven batting. A batt of 60 percent floss and 40 percent synthetic fiber had an insulative capacity comparable to Thinsulate and withstood dry cleaning just as well. Researchers are currently evaluating a batt containing 85 percent floss.

Natural Fibers Corporation, the University of Nebraska, USDA's Cooperative State Research Service, and four Nebraska farmers are working together to over-

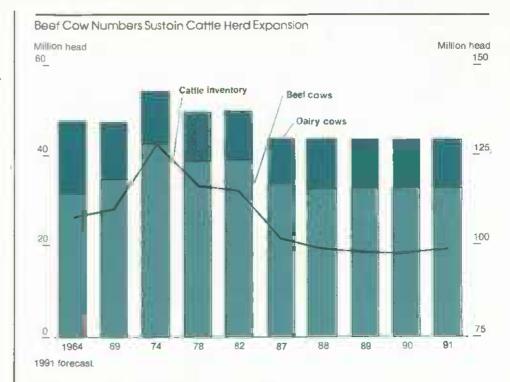

come the technical barriers to milkweed production and product use. Short-term research priorities include:

- improving yields through plant selection and disease control;
- documenting floss characteristics like fiber length, fineness, and maturity, using techniques developed by the cotton and wool industries; and
- preventing fiber matting in loose-fill products (in items like comforters and jackets, 100-percent milkweed floss tends to mat together and form lumps with use and cleaning).

As yields and production increase, milkweed floss could be competitive in higher volume, lower value markets, such as textiles and high-quality papers. Adding floss to tissue paper, for example, makes it softer. In addition, milkweed floss absorbs 75 times its weight in liquid once the fibers are stripped of their wax. Because of this property, possible uses include disposable diapers and other superabsorbent products. [Lewrene Glaser (202) 219-0888]

Alternative Forage Acreage Expanding

rop production is the primary use of the vast U.S. agricultural land base, with cattle and other livestock production a residual user. In 1987, 305 million acres were in principal crops, 656 million in pastures and ranges, and 236 million in forest, the Conservation Reserve Program, and idled acreage. Cattle can be maintained on the vast noncropland forage base and on crop residues, exploiting both these extensive resources for a high-value food product—meat.

Much of the grazing land is either acreage that is temporarily removed from crop production, or land that remains in grass because it is too poor in quality or too fragile for crop production. Poor moisture conditions, rocky or uneven topography (subject to erosion if cropped), or tree or forest coverage keep much of this land from being used for crop production.

However, both the forage base and the beef production mix have shifted, and changes within each of these two broad categories have been even more dramatic. The shift has resulted in an expanding forage base at the same time the cattle industry is moving toward increasingly heavy, but leaner, fed cattle at slaughter.

June Pasture & Range Conditions Good

Pasture and range conditions on July 1 were rated good to excellent, the highest rating for this date since 1983 and much improved from the poor-to-fair conditions reported in most of the country last fall through mid-winter. While drought is a fact of life for many cattle operators, the past decade has been especially dry.

Dry conditions were particularly pervasive in the Western states during the 1980's. However, reduced cattle inventories and a broader forage base from crop acreage have provided an important buffer in drought-designated areas, reducing forced liquidation of the beef breeding herd.

Hay acreage is another important component of the forage base in the cattle sector. Harvested hay allows the producer to support more cattle on pastures and ranges during the better growing seasons by providing an additional forage supplement for nutritional needs during the nongrowing season and during severe winter weather.

Hay acreage has increased since the 1988 drought that resulted in sharply reduced hay stocks. The May 1 stocks were nearly unchanged from a year ago, but up 55 percent from the 1989 low. Area for harvest is expected to rise 1.5 million acres this year as cattle producers ensure adequate forage supplies to support an expanding cattle inventory.

Farm Act Opens Up More Forage Acreage

Forage land available for cattle raising is largely dependent on the demand for crop acreage. However, in recent years the forage base has been further expanded, particularly in drought designated areas. This expansion is due to grazing provisions first enacted in the 1985 farm act and continued in the 1990 legislation.

Land idled under the Acreage Reduction Program and paid land diversion scheme may be grazed during the seven nongrowing months—October to April in most areas. Producers are required to maintain sufficient growth of the mandatory cover crop to conserve soil and water for the idled cropland to be grazed or harvested for hay. Although much of this land is not fenced, it does provide an excellent emergency source of pasture or hay in areas where drought has reduced forage supplies.

Long-term Conservation Reserve Program (CRP) acreage has also provided an additional source of valuable forage in drought-declared areas. The acreage enrolled in the CRP has expanded steadily since enrollment began in 1986. Through this summer, 34.5 million acres have been accepted for enrollment,

Pasture & Range Acreage Were Steady in 1980's

While grazing and/or haying on set-aside or conservation acreage has expanded, permanent pasture and range acreage (the main sources of grazing) have shown a slight downward trend. Cropland pasture, with stocking rates of 2 to 4 acres per cow, is the most productive acreage. This acreage has declined from the 1969 peak of 88 million acres as more acreage was bid back to crop production to satisfy an expanding export demand for grain. Cropland pasture remained unchanged in the 1980's at 65 million acres.

Similarly, grassland pasture and range also have declined since the 1960's. However, since 1969 the acreage has remained between 587 and 598 million acres. This acreage has long served as the primary resource base for the beef cattle industry. The amount of this land on which beef cattle can graze continually (carrying capacity) varies from 5 acres to several hundred acres per cow, depending on the region and length of growing season.

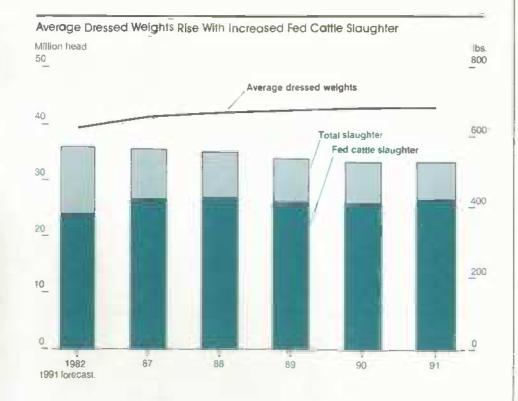

Forest land for grazing has declined steadily since the 1960's. While representing a significant proportion of the nation's agricultural acreage, forest land is limited in total carrying capacity and grazing is highly seasonal in most areas. Cropland pasture, while representing a much smaller proportion of the total acreage, makes a comparatively greater contribution to beef production. However, use of forest land for grazing can be very important in some areas, particularly in the West and Southeast.

Herd Expanding, Cattle Mix Shifting

Cattle inventories have been modestly rising since the cyclical low of 98.2 million head was reached at the beginning of 1989. Adjustments have continued within the caule inventory as the industry has attempted to increase productivity, better utilize available resources, and hold costs down. These shifts are expected to continue as pork and poultry supplies increase at low prices relative to beef.

Although the beef cattle inventory has largely been declining for the last two cattle cycles, beef production has remained in the range of 21 to 24 billion pounds per year during the 1980's. Throughout this period. fluctuations above 23 billion pounds have been largely due to increases in nonfed steer and heifer, and cow slaughter associated with herd liquidations.

Alternately, production has been maintained in recent years by channeling nearly all steers and heifers through feedlots, including an increasingly large proportion of the calves that were previously

slaughtered to produce veal. In 1990, fed steer and heifer slaughter accounted for nearly 80 percent of commercial cattle slaughter, up from an average of 75 percent in the early 1980's. The remainder consisted of cull dairy and beef cows, buils, and stags.

As this shift occurred, commercial slaughter weights increased, as steers and heifers produce heavier and higher yielding carcasses than the cull breeding stock.

Higher Weights, Output Offsetting Smaller Herds

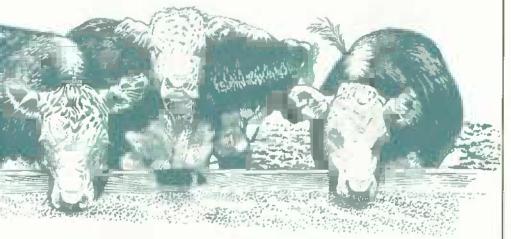

Commercial dressed weights averaged 624 pounds in 1982, but are likely to average well over 680 pounds in the 1990's. Fed cattle marketings have remained within 2 million head of 26 million head per year since the early 1980's. At the same time, the amount of fed beef produced has increased, as slaughter weights have risen dramatically, nearly keeping pace with population growth.

Slaughter weights have also shifted upward due to changes in the genetic mix of cattle as producers concentrate on increasing production efficiency while reducing the amount of trimmable fat. Present feeding technologies and genetic changes, along with increased emphasis on producing lean beef, are resulting in cattle being slaughtered at heavier weights with fewer overfinishing problems. In fact, as weights have risen at a record pace over the past several quarters, feedlots have remained very current. Even as the proportion of fed beef marketed from feedlots has risen, the advances in genetics and feeding technology have resulted in little change in the amount of grain used in producing the heavier weights. Beef calves today are weaned at much heavier weights and increasingly are grazed as stocker-feeders to achieve even heavier weights before being placed on feed. Consequently, the amount of grain fed per pound of beef produced has declined and leaner, more efficient cattle are being produced.

Forage Supplies Adequate Through the 1990's

As the cattle industry continues its modest expansion, and stocker-feeder cattle are grown to heavier weights before being placed on feed, increased pressure will be placed on available forage supplies later in the decade. Although excess forage capacity will be more than adequate for expected expansion through the mid- to late 1990's, pressures on resources will become evident, particularly during periods of drought.

Herd expansion pressures are likely to be muted as the CRP acreage begins to come out of contract in 1996. Little of this land is likely to be needed for crop production and will probably remain in conserving uses with good forage cover, with some acreage shifted to trees. [Ron Gustafson (202) 219-1286]

World Agriculture & Trade

Ag Products Expand Fertilizer Trade

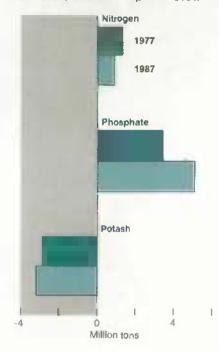

International markets provide important direct and indirect outlets for the U.S. fertilizer industry. In addition to the direct trade in fertilizer materials, an "indirect" trade in fertilizer is generated by agricultural commodities produced for export. While fertilizer use per unit of output generally decreased between 1977 and 1987, research shows that the share of fertilizer nutrients used on exported crops increased.

Fertilizer intensity is a measure of the fertilizers (nitrogen, phosphate, and potash) used to produce a unit of agricultural output. Food and feed grains have the highest fertilizer intensity. Fertilizer intensity dropped during 1977-87. For example, 229 nutrient tons of nitrogen were used to produce \$1 million of feed grains in 1977. By 1987, only 187 nutrient tons were required to produce the same output (in constant 1977 prices).

In 1987, the U.S. exported 4.17 million tons more phosphate material than it imported. By contrast, net imports of nitrogen and potash stood at 1.1 million and 3.7 million nutrient tons. Net direct imports of potash changed little from

World Agriculture & Trade

Net Direct Exports of Phosphote Grow

1977, while net direct imports of nitrogen nearly doubled. Net direct exports of phosphate likewise increased.

"Indirect" Trade Adds To Exports

Indirect trade in these fertilizer materials, however, changes the net export picture. When both direct and indirect trade in fertilizer are considered, the U.S. has even larger net exports of phosphate. Its net imports of potash, the largely foreign-dependent material, are smaller, and it switches from a net importer to a net exporter of nitrogen.

ERS research found that U.S. farmers used 2.1 million nutrient tons of nitrogen, 1.3 million tons of phosphates, and 1.2 million tons of potash to produce agricultural exports worth \$23.6 billion in 1977.

If the \$6.7 billion of U.S. competitive agricultural imports in 1977 had been produced domestically, it is estimated that 245,000 tons of nitrogen, 142,000 tons of phosphates, and 136,000 tons of potash would have been used. So, net indirect exports of fertilizer nutrients for 1977 amounted to 1.9 million tons of nitrogen, 1.1 million tons of phosphates, and 1.1 million tons of potash.

The U.S. clearly used more fertilizer nutrients in producing exports than it saved on imports in both 1977 and 1987. One reason is that U.S. farm exports are more fertilizer intensive than imported commodities. In producing the \$27.9 billion of agricultural products the U.S. exported in 1987 (in constant 1977 prices), farmers used 2.4 million nutrient tons of nitrogen, 1.1 million tons of phosphates, and 1.1 million tons of potash.

The quantity of fertilizer materials that would have been necessary to produce the \$9.7 billion of U.S. farm imports in 1987 was considerably less. The net indirect export of fertilizer nutrients was 2 million tons of nitrogen, 894,000 tons of phosphates, and 578,000 tons of potash.

If direct and indirect fertilizer exports for 1987 are taken together, U.S. net exports of phosphate materials rise to 5.1 million tons. Instead of a net importer of nitrogen, the U.S. becomes a net exporter of close to 1 million tons, and net imports of potash are reduced from 3.7 million tons to 3.1 million.

Fertilizer Intensity of Exports Has Grown

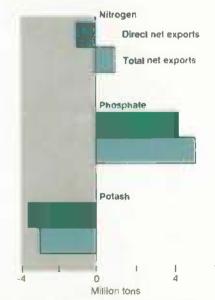

Although agricultural exports in 1987 were higher than in 1977, lower phosphate and potash input were required. Also, total fertilizer use for all farm production in 1987 was lower than in 1977, but the share of fertilizers used for export crops increased. In 1977, the

proportions of nitrogen, phosphates, and potash used for exports were 22, 24, and 22 percent. Ten years later, the percentages stood at 27, 27, and 26.

These changes reflect several influences. More fertilizer-intensive commodities such as food grains, feed grains, oil crops, and cotton and their products were exported in 1987 than in 1977. This parallels earlier findings that U.S. agricultural exports are more land intensive than imports (see AO, April 1991).

Net exports of phosphate increased from 1977 to 1987, while net imports of potash decreased slightly. Although fertilizer intensity generally decreased during this period, the percent of fertilizer nutrients directly and indirectly exported increased. The indirect trade in fertilizer generated by major U.S. agricultural export commodities provides important markets for the fertilizer industry. [Chin Lee (202) 219-0785 and Harold Taylor (202) 219-0464] [AD]

Farm Finance

Reform Poses Risk for Rural Banks

ongress is considering several proposals that could radically restructure the U.S. banking system. Commercial banks account for the largest share of credit to farmers (35 percent in 1990) and are the primary source of credit to rural nonfarm businesses. As a result, farmers and other rural residents have a significant stake in the final outcome of the reform debate.

The centerpiece of bank reform, H.R.1505, the "Financial Institutions Safety and Consumer Choice Act of 1991" considers the following major steps:

- recapitalizing the Bank Insurance Fund (BIF),
- restructuring the deposit insurance system,
- reorganizing the Federal bank regulatory agencies,
- removing geographic restrictions on bank expansion,
- allowing banks to diversify their activities, and

 permitting nonfinancial firms to own banks.

Whether all of these issues will be covered in the final legislative package is an open question. The BIF recapitalization is certain to be addressed, and some restructuring of the deposit insurance system is highly likely.

However, possible disagreement among bank regulators (the Board of Governors of the Federal Reserve System, the Federal Deposit Insurance Corporation (FDIC), the Office of Thrift Supervision, and the Office of the Comptroller of the Currency) could stall reorganization of the regulatory system. And controversy surrounding proposals for nationwide banking and removal of the separation between banking and commerce make the outcome hard to predict.

Reform Could Reduce Number of Rural Banks

The vast majority of rural banks are small and serve local markets. Unlike the Bank Insurance Fund, most rural banks are in sound financial shape. And although higher deposit insurance fees will add to operating costs, this would not threaten the overall financial health of most rural banks.

Likewise, removing restrictions on nationwide branching would increase competition for customers in some markets, but the available evidence suggests that most small rural banks would continue to thrive in those markets under the current deposit insurance system.

But if legislation significantly reduces insurance coverage for depositors at most banks while maintaining a "too big to fail" policy for large banks, then nationwide banking, product deregulation, and continued reliance on domestic deposits for insurance assessments could seriously hinder small banks' ability to compete. One result could be a significant reduction in the number of small independent banks, including those serving rural credit needs.

The effect of bank reform on rural borrowers will depend not only on the specific provisions of the final legislation, but on local financial market conditions as well. Because the geographic market for bank loans tends to be fairly small, limiting competition among rural lenders, these banks will tend to pass increases in operating expenses on to their borrowers.

While competition from the Farm Credit System could hold down interest rates on farm loans, lack of competition for nonfarm loans could lead to higher interest rates in some markets if reform increases bank operating costs. This in turn would dampen development prospects of many rural communities.

Bank Insurance Fund To Be Recapitalized

Impending insolvency of the BIF makes recapitalization of the fund critical.

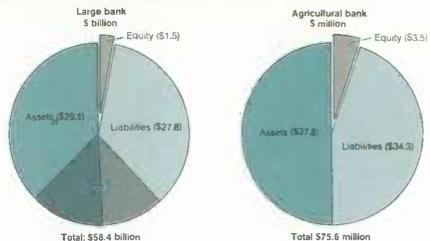

Basing Deposit Insurance Fee on Total Assets Would Reduce Burden on Agricultural Banks

Item assessed	Larg	e banks	Agricultural banks			
	Total fee per bank	Fee per \$100 of assets	Total fee per bank	Fee per \$100 of assets		
	\$1,000	\$	\$1,000	\$		
Domestic deposits	33,042	0.113	76.8	0.203		
Total deposits	41,804	0.143	66.9	0.177		
Total habilities	45,771	0.157	62.4	0.165		
Total assets	65,081	0.154	58.3	0.154		

Large bank figures are based on mean values for the 45 largest U.S. banks, agricultural bank figures are based on mean values for the 4,193 egricultural banks. The analysis holds total FDIC insurance fee receipts constant at the current level.

Farm Finance

Balance sheet of average bank

Based on all U.S. banks with over \$10 billion in assets (large banks) and all banks with greater than the national average ratio of agricultural loans to total loans (agricultural banks)

Assets of the BIF are comprised of fees paid by insured banks and earnings on investments. Its liabilities are obligations incurred when insured banks fail. As the BIF's expenses for bank failures have risen in recent years, its reserves have declined sharply.

At the end of 1990, the BIF had assets of \$16.4 billion and liabilities of \$8 billion, leaving a reserve of \$8.4 billion. The FDIC, which administers the BIF, currently projects the reserve will be depleted in 1991 and that the BIF will have a deficit of \$11 billion by the end of 1992.

Since the FDIC's working capital depends on the size of its reserves, in the absence of recapitalization the FDIC would soon be unable to close insolvent banks. The result threatens a replay of the savings and loan debacle of the 1980's, when insolvent thrifts lost additional billions because the federal agency that insured their deposits could not afford to close them.

To avoid this situation, pending legislation would give the FDIC increased temporary funding for the timely closing of failed institutions. The deposit insurance fee paid by banks to the FDIC is a fixed percentage of total domestic deposits. To compensate for the depletion of bank insurance fund reserves, Congress in 1989 raised the insurance fee. The fee increased 177 percent between December 1989 and July 1991, to \$0.23 per \$100 of domestic deposits.

If the typical agricultural bank absorbed the entire increase in operating cost from retained earnings, its annual lending could decrease \$185,000 relative to the pre-1990 fee. However, the reduction in lending would reach \$380,000 if the entire drop in retained earnings were absorbed by the loan portfolio.

The 1989 legislation also lifted the statutory ceiling on deposit insurance fees, opening the door to additional increases in the future.

New Fee Structure May Reflect Risk

The deposit insurance system currently places a disproportionate burden on banks with relatively safe portfolios and on small banks in general. Deposit insurance fees are unrelated to the riskiness

of bank assets, creating a situation in which bank failure becomes more likely.

If a bank is having financial problems, management may make riskier loans and investments in the hope of earning the higher returns needed to grow.

Depositors, insured against loss, have no incentive to monitor a bank's risk-taking. But such a bank pays insurance fees at the same rate as other banks.

Additionally, the deposit insurance fee is assessed only on domestic deposits even though the insurance fund often covers losses on foreign deposits and other liabilities. Large banks hold a smaller portion of their liabilities in the form of deposits than small banks, and many large banks hold significant foreign deposits. Small banks typically do not hold foreign deposits.

As a result, under the current insurance scheme small banks and those least likely to fail pay a higher price for insurance than larger banks and those taking significant risks.

The proposals for restructuring deposit insurance operations include scaling insurance fees to the riskiness of a bank's portfolio, assessing fees against bank asset levels instead of deposits, requiring deposits to be fully backed by Treasury securities, and assessing fees on foreign deposits.

While the final form of restructuring isn't yet known, there is some chance that the new premium structure will more closely reflect risk. Given the current insurance scheme, restructuring the system should benefit agricultural and rural banks.

"Too Big To Fail" Policy Hurts Small Banks

From the perspective of small banks, the inequities of the current insurance fee schedule are compounded by regulators' decision that some banks are "too big to fail" because of the threat to the stability of the entire banking system. In practice, deposits in excess of the \$100,000 insurance limit are reimbursed when a big bank fails.

Farm Finance

Small Banks Pay Higher Per-Dollar Insurance Fee

Several aspects of the balance sheets of small and large banks effectively shift the burden of deposit insurance funding toward small banks. Critical differences between the balance sheet of an average agricultural bank and a large commercial bank include;

- the small bank's much higher proportion of domestic deposits to total liabilities,
- absence of foreign loans and deposits in small banks, and
- their higher proportion of capital to assets.

A comparison of the ratio of insurance fees to assets for a typical large bank and an agricultural bank reveals important differences. Because only domestic deposits are considered when assessing deposit insurance fees, agricultural banks on average pay a much higher fee per dollar of assets than large banks, and for more limited insurance coverage.

Assessing either total assets or total liabilities could distribute the burden more equitably. This change, however, would still not adjust for the differential risk associated with the portfolio of income-earning assets of each bank.

In contrast, when a small bank fails, some or all of the uninsured deposits can be lost. The competitive effects of "too big to fail" policies are currently muted because depositors can have multiple insured accounts at the same bank, providing insurance coverage far exceeding the \$100,000 limit at even the smallest bank.

But deposit insurance reform could limit coverage of multiple accounts, making it harder for small banks to attract and hold large deposits. Proposals limiting coverage to \$100,000 per depositor at any one bank are currently being considered. And some proponents of this change would like a lifetime limit of \$100,000 in insurance coverage for all of a depositor's accounts, even if they are distributed among several financial institutions.

Other proposals would severely limit "too big to fail" policies in an effort to provide a more "level playing field" for banks of all sizes. Given the cost of the savings and loan bailout, considerable sentiment exists for limiting the Federal government's exposure to similar losses in the banking industry.

Since a "too big to fail" policy effectively insures all deposits at the biggest banks, uninsured deposits are likely to gravitate to those banks as long as the policy is the norm. Coverage limitations would actually help large banks, even those in danger of failing, to acquire more funds at lower interest rates than smaller banks, as long as depositors believed large banks are not allowed to fail. [Doug Duncan (202) 219-0893 and Patrick Sullivan (202) 219-0719]

General Economy

A New Expansion Underway?

second-quarter data strongly suggest that the recession ended sometime in April or May. Production rose during those months, in May consumer spending posted its biggest gain so far this year, and the second-quarter job decline was the smallest since the recession began. Despite the upward tilt of recent economic indicators, the economy is still operating at low levels and the unemployment rate is relatively high.

Many analysts believe the economy is poised to recover in the second half of this year. Interest-sensitive sectors, especially residential housing and automobiles, are likely to rebound most dramatically. However, the revival in U.S. spending could push the net export deficit slightly higher. Weak demand last year caused real imports to drop in the fourth quarter and the first quarter of this year, generating the first quarterly real net export surplus since the middle of 1983.

Inflation should remain moderate, barring any unanticipated rise in energy or food costs. The relatively high unemployment rate and low rates of

capacity use in many industries will dampen inflationary pressures. Continued moderation of core inflation would allow interest rates to drift lower, although rapid growth would tend to increase credit demands and push rates up. If lower inflation appears to be permanent, long-term rates may drop somewhat more than short rates.

Production Climbs & Job Losses Slow

Industrial production rose 1.5 percent in the second quarter, the first quarterly increase since third-quarter 1990. Rising auto production helped spur the overall increase. Capacity utilization remained relatively low in the second quarter, about 5.8 percentage points below the peak received in the second quarter of 1989.

The rise in manufacturing production bodes well for other sectors of the economy. The manufacturing sector, for example, buys about 25 percent of the services the economy provides.

Total nonagricultural payroll employment continued to decline in the second quarter, but at a slower rate than previously. In fact, employment rose by 119,000 jobs in May, the first increase since the beginning of the recession. Furthermore, the 50,000 June job losses were substantially fewer than the 144,000 average monthly jobs lost over the past 11 months.

Overall, employment in June was almost at the same level as in March. Service-producing employment increases over the past 2 months boosted the May gain and offset some of the June decline. In the manufacturing sector, average weekly hours of production or nonsupervisory workers increased in the second quarter, the first rise since the beginning of the recession.

Despite the current job gains, the unemployment rate remains relatively high. At 6.8 percent for the second quarter, the rate was 1.5 percentage points above the first quarter of 1990. But during recoveries, improvement in the unemployment rate typically lags increases in the number of jobs, as rising job prospects bring more people into the labor force. The larger number of people looking for work tends to keep the unemployment rate from falling.

Inflation Remains Moderate

Steady overall consumer price inflation in the second quarter masked substantial variation among the components. Prices rose 3.6 percent at an annual rate in the first quarter, and 2.1 percent in the second. Energy prices jumped in May after falling for 5 straight months. Food prices rose more sharply in the second quarter than the first.

The core inflation rate, measured by consumer prices excluding food and energy, was 3.2 percent in the second quarter, well below the 6.9-percent pace of the first. The decline in the core inflation rate reflects stack in the overall economy and the indirect effects of falling energy costs since the fourth quarter of last year.

Short-term Interest Rates Dropping

Short-term interest rates continued to slide in the second quarter, reaching their lowest levels since the middle of 1987. The Federal Reserve appears to be targeting the Federal funds rate—the rate at which banks lend among themselves—at about 5.75 percent, approximately 2.5 percentage points below last October's rate. The falling Federal funds rate has translated into lower short-term rates overall, including a lower bank prime

Long-term rates have been relatively stable since December 1990. Analysts have suggested that the primary reason long rates have not fallen in lockstep with short rates is a concern that the economic recovery would accelerate inflation.

Comparing Farm & Nonfarm Rates

Not all sectors of the economy encounter the same interest rates. Preliminary analysis of the Fed's bank lending data suggests that farm interest rates are slightly higher on average than rates for commercial and industrial borrowers. Also,

General Economy

farm rates tend to be less volatile than rates for commercial and industrial borrowers.

In general, changes in farm rates have mirrored movements in commercial and industrial loan rates. However, the relationship between farm rates and other commercial rates was notably different in 1977-81 than in the 1982-90 period. During 1977-81, agricultural loan rates were quite close to commercial and industrial rates. On average, commercial loan rates were 43 basis points above agricultural loan rates.

In the midst of the 1981-82 recession, however, commercial rates began to drop significantly below farm loan rates. The widest spread, 366 basis points, was in August 1986. The spread narrowed to 97 basis points in May 1989. The latest report, November 1990, shows a divergence of 174 basis points between agricultural and commercial loan rates.

About the Data From The Federal Reserve...

Since 1977, the Federal Reserve has surveyed commercial banks on their terms of lending for both commercial-industrial and agricultural activities. The survey is conducted in the first full business week of the second month of each quarter. About 340 commercial banks complete the survey, with 250 banks reporting loans to farmers.

The survey provides details including the number of loans made and their amount, average loan size, average maturity, and the effective interest rate. In addition, the loans-to-farmers category divides the information by loan size and bank size, and includes interest rates by loan purpose (e.g., feeder livestock, farm machinery and equipment). Excluded from the survey are mortgage loans, purchased loans, foreign loans, and loans of less than \$1,000.

Preliminary research using 1977-90 data shows that each percentage point change in commercial and industrial loans is associated with a change of about 70 basis

sociated with a change of about 70 basi points in the rate for agricultural loans. Between 1982 and 1990, this rose to about 81 basis points.

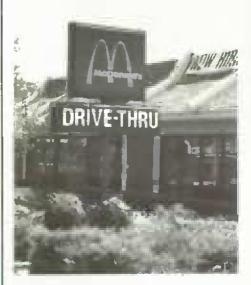

At least two major factors could explain the discrepancy between agricultural and other commercial rates. Lending for agricultural purposes may be seen by banks as more risky than lending for commercial and industrial activities. Second, the typical size of loans for agricultural purposes is much smaller than commercial and industrial loans. Explaining these differences will be the next step in the analysis.

Further Fall in Farm Rates Expected

While the most recent data on farm lending rates from the Federal Reserve Board are for November 1990, movements in the prime rate indicate farm lending rates have declined thus far this year. In the first 6 months of this year, the prime rate declined 1.5 percentage points, while farm loan rates are likely to have fallen slightly more than 1 percentage point.

Whether interest rates rise or fall in the second half depends largely on how quickly the economy recovers and what happens to inflation. Over the first 6 months of comparable recoveries, the bank prime rate has declined about 72 basis points on average. If previous recoveries are any guide, this suggests a further decline in agricultural interest rates in the second half. [Elizabeth Mack and Ralph M. Monaco (202) 219-0782] NO

Food & Marketing

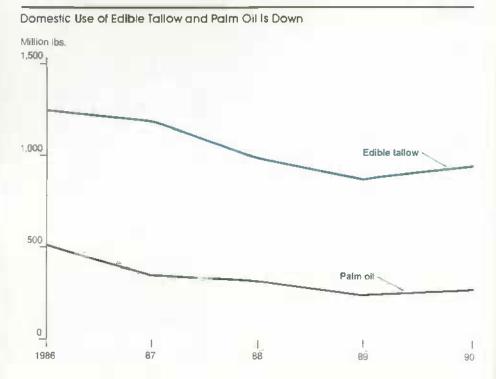

Fast Food Changes Hit Fats Market

ust over a year ago, major fast food restaurants announced they would substitute vegetable oils for the edible tailow used to cook french fries. Vegetable oil markets have adjusted to the new market structure but the tailow industry is still reeling from a substantial cut in demand.

Domestic disappearance of edible tallow fell to 876 million pounds in 1989/90, down sharply from the 1985/86 peak of 1.65 billion pounds. This season, lower prices for edible tallow have boosted use slightly despite consumer preferences for vegetable oils. An increase in domestic disappearance to 950 million pounds is forecast for 1990/91, but exports will be weaker.

Except for some shortrun disruptions late last summer, when the price of corn oil jumped 3 cents a pound and some food manufacturers faced temporary shortages of corn oil, the vegetable oil sector has adapted to the fast food shift with minimal problems. Domestic use of corn and cottonseed oil is forecast to increase in 1990/91.

Food & Marketing

Animal fats—edible tallow, lard, and butter—have had a prominent place in the American kitchen for centuries, and are likely to remain important ingredients in foods and cooking for years to come. Vegetable oils and the shortenings manufactured from them are relatively recent arrivals in home and restaurant kitchens. Oils like canola (another name for the edible varieties of rapeseed oil) are even more recent newcomers.

Health Concerns Force Change

Frying with animal fats has long been popular among cooks and diners because fat cooks fast and produces foods with an attractive appearance and an appealing flavor. Tallow also costs less per pound than vegetable oils and is generally considered more "durable" than vegetable cooking oils and shortenings. Until recently, some of the biggest users of tallow have been commercial establishments, particularly fast food restaurants in preparing french fries.

The health concerns of consumers have led to a notable shift in attitudes toward fats and oils. Attention first focused on tropical oils (palm, palm kernel, and

coconut oils) because of their relatively high saturated fat content. Food manufacturers began to replace tropical oils, and the claim "Contains no palm oil" appeared on a number of product labels. Domestic use of palm oil, nearly 600 million pounds in 1985/86, fell to just over 250 million in 1989/90.

Attention then shifted to the use of tallow by the fast food industry. In the summer of 1990, three major fast food restaurants responded to consumers' concerns about possible health risks of french fries cooked in tallow. Within a few days of each other, Burger King, Wendy's, and McDonald's announced they would shift to vegetable oil for their french fries. A fourth major chain, Hardee's, had already made the switch to vegetable oil. Although some restaurants still use tallow, their prospects for growth and influence are small compared with the big chains.

Nutrition data from Burger King, Wendy's, and McDonald's indicate that the change in frying fats reduces the saturated fat content of their french fries by about 50 percent.

Americans' average fat intake, expressed as the proportion of calories provided by fat, fell from 41.8 percent in 1977 to 37.3 percent in 1985. Despite that reduction, fat intake remains above the level (30 percent or less) recommended by the National Research Council of the National Academy of Sciences and by the American Heart Association.

Tough Adjustment For Tallow Industry

The edible tallow industry has had to adjust to the switch by fast food chains to vegetable oils. The three chains that announced the shift last summer accounted for about 30 percent of the domestic edible tallow market. Sudden market changes of this magnitude are rare in the food industry, particularly when the shift is to a substantially more costly ingredient.

Complicating the adjustment is the fact that the supply of edible tallow is inclastic with respect to the price of fats and oils. This means that the supply does not decrease as prices drop. The reason is that tallow is a by-product of the production of meat.

One avenue of adjustment for tallow is to divert more to the inedible market, where it is used as an ingredient in animal feeds, as an input for soap manufacture, and for other purposes. These outlets, however, bring a much lower price. The

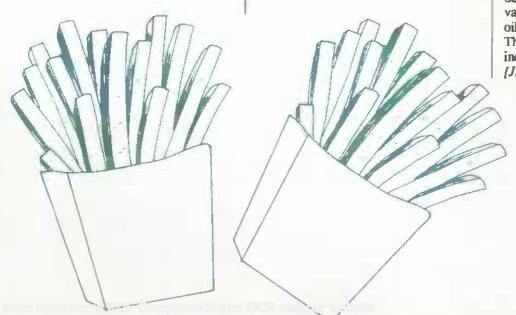

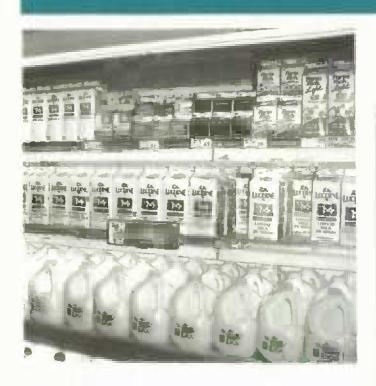

Impact Is Lower on Vegetable Oil Market

The shift by the fast food industry apparently has had less impact on the vegetable oil industry than on the edible tallow markets. The fast food industry switched about 250 million pounds of demand to cottonseed oil, corn oil, and soybean oil. Vegetable oils are generally good substitutes for one another although each has its unique flavor and cooking properties.

Soybean oil is the most plentiful oil in the U.S. and dominates the domestic market. The U.S. produces large quantities of soybean oil because it grows soybeans not only for oil but also for protein meal to feed livestock. On average, 35-40 percent of the bean's value is derived from the oil value. Because the supply is so large, even if the edible tallow used by the major fast food chains were replaced with soybean oil alone, soybean oil use would increase by less than 2 percent, and the price would only increase marginally.

But most of the switch in the fast food market was to corn and cottonseed rather than soybean oil. These oils are produced from crops that are grown not for their oil content but for the feed and industrial value of the grain or the fiber value of the lint. Like edible tallow, the oils these crops yield are by-products. Their supply depends on the demand for industrial products of corn and cotton. [Jim Schaub (202) 219-0840]

The Milk Inventory Management Study

airy policy is again in the spotlight. The 1990 farm bill required USDA to submit a report to Congress assessing alternative milk inventory management programs. The Milk Inventory Management Report has generated considerable interest on Capitol Hill and in the dairy and related industries.

The report evaluated four general alternatives to the current dairy program, each with the objective of avoiding large milk surpluses. The approach was to quantify the potential effect of each alternative on milk production, use, and prices, compared with baseline projections under current policies. Each of the four alternatives was found to have shortcomings, and USDA concluded that the current dairy program measures up well against the options studied.

USDA released a preliminary analysis of milk inventory management programs on May 15, 1991. Following a comment period, the Department prepared and delivered the final Milk Inventory Management Report to Congress on June 14. Agriculture Committee hearings on the report were held in the House of Representatives (June 18) and in the Senate (June 19). The testimony—and response in the industry press—reflected a mixed response to USDA's recommendations and analysis.

Excess Supply Anticipated

By most indicators, 1990 was a good year for the dairy industry. Milk prices reached near-record levels, and the financial situation of dairy farms improved. However, increasing milk production in the second half of 1990 and long-term projections of milk supply and demand raised concerns about potential oversupply.

In the Food, Agriculture, Conservation, and Trade Act (FACT Act) of 1990, Congress mandated that USDA conduct a study of milk inventory management programs. At least two programs were to be studied, 1) a target price/deficiency payment plan, and 2) a reclassification plan, commonly called the Class IV plan. Congress directed that no proposal involving a government buy-out of dairy cows was to be considered, even in tandem with other program provisions. Also, no program which reduced the price support level could be included in the study.

Milk inventory management proposals were also solicited from the public. Seventy-seven proposals were received by the February 6, 1991 deadline. In addition to target price/deficiency payment and Class IV programs, proposals offered by the public were: 1) two-tier pricing, 2) milk marketing diversion, and 3) demand-increasing policies.

Four Program Types Evaluated

Demand-increasing proposals were eliminated from consideration since they were, in general, not comprehensive programs, but facets of some other plan. Four program types were selected for detailed analysis, and were compared to the present policy. Currently, the price of milk is supported at a rate of not less than \$10.10 per cwt. Unlimited government purchases of butter, cheese, and nonfat dry milk ensure that minimum milk support prices are attained.

In addition to the price support program, but not specifically evaluated, are 42 Federal milk marketing orders that establish minimum prices for milk according to three classes of use. Under an order, processors pay the lowest price for milk used in hard products (Class III milk)—butter, cheese, and nonfat dry milk. The next highest is for milk used in soft products, such as yogurt or ice cream (Class II). Milk used for beverage purposes has the highest value (Class I).

Target price/deficiency payment—Target price/deficiency payment programs are designed to provide income support for milk producers through direct payments equal to the difference between the target and market prices of milk. Individual producers may or may not be required to reduce their marketings in order to be eligible for payments. If a reduction were required, marketing bases or quotas would have to be established. All producers would receive the same payment rate per cwt of

Rating the	12 Milk	Inventory	Management	Program
Options 1/

Two-tier \$13,10, quota (+ 0), variable assessment 3/4/	-5
Marketing diversion \$10,10	6
Marketing diversion \$13.10, assessment	-5

1/ The ratings are the sum of results for individual criteria. Highest positive number equals highest rank, 2/ Dollar figures refer to per-owt target prices, support levels, or assessments: 3/ Quota equals commercial use • Food and Nutrition Service purchases + Commodity Credit Corporation purchases, in billions of pounds: 4/ Variable assessment equals the difference between the U.S. manufacturing grade and international Prices.

milk marketed, but it would not be determined until the end of the year. Deficiency payments would increase with marketings unless a limit were imposed. The market price used for payment-rate calculations would be the U.S. all-milk price,

Class IV—Reclassification plans would establish a fourth class of milk. Class IV milk would be used for the manufacture of butter, cheese, and nonfat dry milk to be disposed of internationally or otherwise outside normal domestic commercial channels. An assessment, levied on all milk marketed, would reflect the cost of disposal. Reducing the supply available on normal commercial markets would prevent surpluses from depressing prices.

Two-tier pricing—Two-tier pricing plans would require mandatory milk marketing bases and quotas for individual producers. The size of the quotas would depend on estimates of market requirements. A market price, supported by reduced marketings due to quotas, would be paid on milk marketed within the quota. The producer would pay an assessment on marketings of milk in excess of quota. This second-tier price would usually be low enough to discourage production beyond commercial use and a specified level of government purchases. The assessment on over-quota marketings would be remitted to the Commodity Credit Corporation to offset government program costs.

Milk marketing diversion—Under milk marketing diversion programs, participating producers would be paid to reduce marketings. Participants would be subject to individual marketing bases and quotas. The amount of the diversion payment rate would be known in advance and could be directly linked to contracted marketing reduction rates. Producer assessments could be used to offset program costs.

Evaluating the Programs

The four program types all draw upon past (and present) agricultural policies. Of the four, only the marketing diversion type has a direct link to a past dairy program, the Milk Diversion Program of 1984. The Class IV plans involve modifications of classified pricing, the system currently used under milk marketing orders. Target price/deficiency payment programs have been widely used for grains and cotton. Finally, a two-tier pricing program was used for wheat in the 1960's, and is now used for peanuts and tobacco.

A 21-member team representing seven USDA agencies undertook the study. Twelve individual options were analyzed and included in the final report: four target price/deficiency payment plans, three Class IV programs, three two-tier pricing plans, and two milk marketing diversion programs. The 12 options represented "composite" programs that contained the unique features of individual proposals. A range of support price options was considered for each program type.

The permanent authority for the milk price support program (Section 201 of the 1949 Agriculture Act) states that the objectives of the program are "to assure an adequate supply of pure and wholesome milk" and "to meet current needs, reflect changes in the cost of production, and assure a level of income adequate to maintain productive capacity sufficient to meet anticipated future needs."

Evaluating a particular program's potential to meet such broad policy objectives is difficult. The 1990 FACT Act listed 12 criteria for evaluating proposed milk inventory management programs. The last of the criteria was a general one for capturing other issues deemed appropriate by the Secretary of Agriculture. For purposes of the inventory management report, 3 specific program criteria were assigned to this category, resulting in a total of 14:

- ability to limit government purchases to 6 billion pounds (milk equivalent, total milk solids basis) in a calendar year;
- speed and effectiveness in reducing excess milk production;
- effectiveness in sustaining reduced production for at least 5 years with or without continuation of the program;
- impacts on regional price, revenue, and supply;
- impacts on national producer income and government expenditures;

- impacts on the rural economy and the maintenance of family farms;
- effects on the availability of wholesome dairy products for domestic and foreign nutrition and food assistance programs;
- technological innovations;
- effectiveness in reducing butterfat production and increasing milk's protein content;
- ability to cushion temporary increases or decreases (shocks) in milk production;
- impacts on the U.S. livestock industry;
 - (1) consistency with international obligations and impacts on international trade:
 - (2) impacts on consumers, including levels of consumption and costs; and
 - (3) effects on the long-term efficiency of the U.S. dairy industry and the competitiveness of dairy with nondairy products.

Baseline projections were made for milk production, use, prices, farm milk receipts, retail value, and government costs under the current dairy support program for fiscal 1991/92 through 1996/97. The same indicators were estimated for each program option, using a simulation model, and the results were compared with the baseline.

These projections were, in turn, used to evaluate impacts on other industries and entities specified in the criteria of the FACT Act. Models developed by ERS for other USDA programs were used to evaluate impacts on the red meat and poultry sectors and on rural economies.

Rating System Identifies Drawbacks

A rating system was developed by USDA analysts to evaluate each proposed program's effect on production, use, prices, farm receipts, retail value, and government costs. In addition, their impacts on the Food and Nutrition Service's (FNS) food programs, livestock and poultry industries, the rural economy, and compatibility with U.S. international trade obligations were considered. The rating system provided a systematic and consistent approach for using the 14 criteria to evaluate the programs.

The high support price options of each program type presented difficult tradeoffs. Although they raised farm receipts substantially, they increased consumer costs, decreased domestic consumption, inhibited long-term adjustments in production, processing, and consumption, and were not altogether compatible with U.S. trade responsibilities.

With the exception of the reclassification and milk diversion plans, high support price options resulted in detrimental near-term consequences in the beef industry, with additional dairy cow kills reaching more than 625,000 head. If programs were

implemented to remove the extra beef from domestic markets, they would infringe on U.S. trade responsibilities.

High support price options would also reduce FNS food program buying unless special buying features were implemented. Other consequences included consumers' opting for nondairy substitutes in the short term and, in the longer term, manufacturers' developing substitutes similar to oleomargarine in the 1950's.

The lower support price options raised comparable concerns, although to a lesser degree. None of the lower support price options raised farm receipts significantly above the baseline, raising the question of whether the added government interference could be justified.

In light of the problems identified, USDA concluded that the current program "measures up well." Although the program does not guarantee producers a profit, it does provide the market signals individuals need to make decisions, and acts as a price floor to stabilize downswings in prices.

What Are the Hard Questions?

A fundamental objective of all four proposed inventory management programs is to control milk production so that surpluses do not become severe. The dramatic fall in prices from near-record levels of \$13.73 per cwt on average during 1990 to \$11.40 per cwt during June 1991 tends to focus industry and policymakers' interest on the programs' price-stabilizing features.

However, obtaining a milk price increase is not "costless"—taxpayers, consumers, government, even milk producers themselves may be presented with all or part of the bill. The higher the price, and the associated support price beneath it, the higher the cost.

Four concepts are commonly linked with dairy policy alternatives: increased producer income, minimal cost to government, compliance with international obligations, and orientation to market signals other than to government payments. If these are the four major goals of dairy policy, then the hard questions may well be:

- How much of an increase in milk producer income is really warranted?
- Who will pay the costs of increased income for dairy farmers?
- Is the U.S. willing to adopt programs that could put it at odds with the GATT and with its trading partners in an increasingly interdependent world economy?
- What does market orientation mean for an industry that has long depended on government intervention?

Mexico's Economic Reform Shows Results

The government of Mexico is embarked on a course of unilateral economic reform, reversing the direction of inward-looking economic policy pursued most of this century. The government is convinced that freeing up its economy is a precondition for sustained growth and development. The stated objective of the government is to bring Mexico's per capita income level to that of a typical industrial country over the next 20 years.

First discussed in 1985, and initiated in December 1987, policies aimed at fundamental economic reform are moving Mexico toward a more open economy based on free trade and competitive markets. And there is a further commitment not to interfere with the necessary adjustments that this entails. The new policies appear to be improving the efficiency and performance of the Mexican economy.

Although the reforms are not as well publicized as those in Eastern Europe and the USSR, they are as dramatic and as potentially significant for the U.S. Mexico is the third-largest U.S. trade partner and the third-largest market for U.S. agricultural exports. The U.S. purchases half of Mexico's oil exports and over three-fourths of its other merchandise exports, making it Mexico's leading trade partner. Between 1985 and 1989, 65 percent of merchandise imported by Mexico came from the U.S.

The reform process in Mexico, by generating healthy economic growth and encouraging foreign investment, is providing opportunities for increased trade between the two countries. Reform is proceeding as discussions continue with the U.S. on the formation of a North American Free Trade Agreement with Mexico and Canada. The agreement, which would create a free trade area larger than the EC in population and economic activity, could be the first step toward the formation of a Western Hemisphere Free Trade Area. One main objective in seeking a free trade agreement is to institutionalize the reforms already taking place.

In addition, Mexico has joined Costa Rica, El Salvador, Guatemala, Honduras, and Nicaragua to create a free trade zone among these countries by the end of 1996. Although the Mexican government anticipates an increase in trade because of the free trade agreements, the main benefits will come from securing long-term markets for products based on efficient production and market prices, the efficiency gained by deregulating their economy, and large sustainable increases in direct foreign investment, primarily from the U.S.

Output Is Up, Inflation Down

Although real gross domestic product (GDP) in Mexico grew less than 2 percent annually between 1982 and 1988, real GDP grew 3.1 percent in 1989, 3.9 percent in 1990, and is projected to exceed 6 percent annually by the mid-1990's. In addition, investment has increased to 23 percent of national income, up from 18 percent in 1985, and is projected to rise to 25 percent by the mid-1990's.

Mexico's debt-to-GDP ratio fell from 0.80 in 1986 to 0.35 by the end of 1990 and is projected to drop to 0.25 by 1996. The ratio of foreign debt repayments to exports has similarly fallen from 0.44 in 1988 to 0.30 in 1990 and is projected to decline to 0.25 by 1996.

Annual inflation, which peaked at almost 160 percent during 1987, is currently running below 30 percent and is projected to drop to 6 percent by 1995. In addition, the government's deficit has dropped from an average of 12.5 percent of GDP between 1982 and 1988 to under 2 percent in 1991.

Macro Policies Are Reducing Inflation

A major shift in macroeconomic policy in Mexico has been underway since 1987. Fundamental to the shift is a movement from a state-controlled to a competitive economy, driven by private sector growth, international trade, and private investment. The key indicator of the success of the macroeconomic reforms has been a decline in the rate of inflation.

In Mexico, government borrowing is accomplished primarily by printing money, an inflationary practice. When the government deficit rose to 16 percent of GDP in 1987, inflation surged to almost 160 percent. The decline in government borrowing since then, to 3.5 percent of GDP in 1990, relieved pressure on the central bank to print money, and inflation eased.

Exchange rate policy also affects inflation. A rapid devaluation is inflationary for two reasons. First, domestic prices in Mexico increase as prices of imports rise and export sales increase. And second, the money supply increases as U.S. buyers exchange dollars for pesos to purchase more goods from Mexico. And the faster the devaluation, the more rapid the increase in money supply.

The Mexican government has slowed the rate of devaluation of the peso against the dollar to less than 5 percent per year. The long-term objective is to stabilize the peso's exchange rate against the dollar once inflation is reduced to less than 6 percent.

Policies aimed at increasing competition can also help control inflation. The Mexican government is approaching this in three ways: reducing the number of state-owned enterprises, opening domestic markets to foreign suppliers, and eliminating regulations that tend to stifle competition.

Privatization of many government enterprises has reduced the government's need to borrow for three reasons. First, subsidies to government-owned enterprises have been reduced by half since 1987. Second, revenues from the sale of government-owned businesses can be used to reduce government debt. Third, this revenue can be placed in a reserve fund, currently totaling about \$1 billion, to be used as a hedge against future uncertainties.

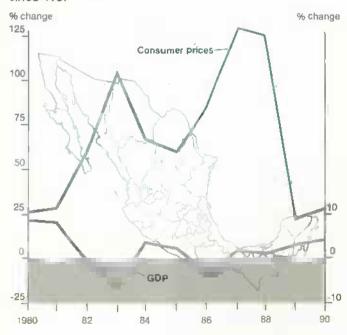

The reduction of Mexico's foreign debt in 1989, under the auspices of the Brady Plan, has had a substantial impact on fiscal and monetary policy, the investment climate, and the outlook for the economy. External debt fell from \$101 billion at the beginning of 1989 to \$87.5 billion by the end of 1990.

Debt reduction has led to the lowering of current repayment obligations. As recently as 1986, repayment of foreign debt took half of all export earnings and contributed to the fiscal deficit and inflation. In 1990, however, debt repayment accounted for only 30 percent of export earnings, and this figure should slip to 27 percent in 1991. The net outflow of resources to service foreign debt amounted to 6 percent of Mexico's GDP between 1982 and 1988, but is now just slightly over 2 percent.

Free Trade, Deregulation, & Privatization Are Key

The substantial change in macroeconomic policies in Mexico has included a radical program consisting of trade reform, sale of public enterprises, deregulation, and encouragement of direct foreign investment.

All imports were subject to licensing in 1982, but by the end of 1989 the licensing requirement applied to only 2 percent of all goods. Current plans call for the total elimination of import licenses over the next 5 years. And while average tariff rates were 85 percent in 1982, maximum rates are currently 20 percent and average rates under 10 percent. Unregulated access to foreign exchange has eliminated an additional import barrier.

The government of Mexico operated 1,155 public enterprises in 1982. Yet only 425 remained at the end of 1990, with another 200 scheduled either for sale or liquidation. These government schloffs include TELMEX (the telephone company), several banks, hotel chains, sugar refineries, steel mills, and insurance companies. Government expenditures to support public enterprises have been reduced sharply since 1988 and will decline further.

Planned government divestitures in 1991 and 1992 include additional nationalized banks, a large insurance company, steel mills, fertilizer plants, a railroad manufacturing company, and the national airline. However, the national petroleum company (PEMEX), which contributes about 20 percent of total government revenue, will remain a public enterprise.

Major reductions in regulations have been instituted in banking and finance, transportation, and insurance, and in the packaging, customs, petrochemicals, sugar, and cocoa industries. The efficiency generated by deregulation explains much of the reinvestment and growth in the Mexican economy at a time of substantial contraction in government expenditures.

Foreign Investment Critical for Growth

One of the most significant results of deregulation has been a rise in direct foreign investment. The objective of the 1989 reform was to match the open trade environment with an open investment climate. Red tape associated with foreign investment was sharply reduced, and more sectors were opened to foreign investment without the requirement of prior approval.

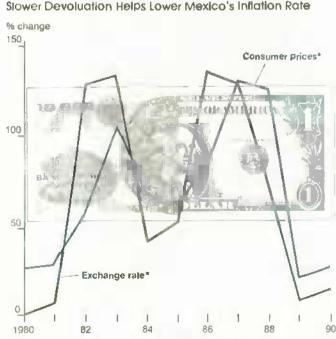

Direct foreign investment is superior to government-guaranteed foreign loans for economic development. Unlike debt, investment has no explicit repayment requirements, and risk is largely transferred abroad. Moreover, investment gravitates to enterprises that have the potential to generate income for repayment.

In addition, the new regulations specify that two-thirds of all new business activities require no approval for start-up. These include projects that are outside major cities, that are financed by investment from abroad, and that will not lead to an outflow of funds from Mexico in the first 3 years of operation. However, businesses related to agriculture must receive specific approval.

Banking Deregulation Stimulates Investment

Liberalization of bank regulations has also been significant. Prior to 1988, the government dictated interest rates, liquidity requirements, and the types of loans a bank could make. In addition, the government used banks to raise capital. Reserve requirements at the central bank, for example, were increased whenever new government financing was needed. Add to this the effect of interest rate ceilings, and the result was little financial activity between the banks and the private sector.

Interest rates have now been largely deregulated and lending is at banks' discretion rather than by government rules. Reserve requirements have been fixed at 30 percent of deposits rather than being subject to arbitrary change. And banking will soon be completely privatized.

*Percentage Change in exchange rate (pesos per dollar) and in consumer prices.

Special Articles

Several important consequences of deregulation are evident. The flow of savings into financial institutions has increased substantially due to the freeing of interest rates and the movement to very high real rates of return from previously controlled rates at negative real returns.

Consequently, credit to the private sector has increased dramatically in real terms, up 67 percent in 1989 from a year earlier and up a further 28 percent in 1990. This has largely allowed private investment to replace government investment, and the expansion of the private sector has encouraged capital from foreign countries to flow into Mexico. ^{1/} Retail costs are based on CPI-U of retail prices for domestically produced farm foods, published monthly by BLS. The farm value is the payment for the quantity of farm equivalent to the retail unit, less allowance for byproduct. Farm values are based on prices at first point of sale & may include marketing charges such se grading & packing for some commodities. The farm-retail spread, the difference between the retail price & the farm value, represents charges for assembling, processing, transporting, distributing. 2/ Weighted average price of retail cuts from pork & choice yield grade 3 best. Prices from BLS. 3/ Value of wholesale (boxed beef) & wholesale cuts (pork) equivalent to 1 ib. of retail cuts adjusted for transportation costs & byproduct values. 4/ Market value to producer for live snimal equivalent to 1 ib. of retail cuts, minus value of byproducts. 5/ Charges for retailing & other marketing services such as wholesaling, and in-city transportation. 6/ Charges for livestock marketing, processing, & transportation.

^{1/} Real Indexes adjust nominal exchange rates for differences in rates of inflation, to avoid the distortion caused by high-inflation countries. A higher value means the dollar has appreciated. See the October 1988 issue of Agricultural Outlook for a discussion of the calculations and the weights used. 2/ Federal Reserve Board Index of trade-weighted value of the U.S. dollar against 10 major currencies. Weights are based on relative importance in world financial markets. P = preliminary.

^{1/} Fiscal 1988 wool & mohair program outlays were \$130,635,000 but include a one—time advance appropriation of \$126,108,000, which was recorded as a wool program receipt by Treasury. 2/ Approximately \$1.5 billion in benefits to farmers under the Disaster Assistance Act of 1989 were paid in generic certificates & were not recorded directly as disaster assistance outlays. 3/ Does not include CCC Transfers to General Sales Manager. 4/ Includes Export Guarantee Program. Export Guarantee Program—Credit Reform. Direct Export Credit Program, Market Promotion Program, & CCC Transfers to the General Sales Manager. 5/ Includes cash payments only. Excludes payment—in-kind in fiscal 83–85 & generic certificates in fiscal 86–90. E = Estimated in the fiscal 1992 President's Budget based on November, 1990 supply & demand estimates. Minus (-) Indicates a net receipt (excess of fepayments or other receipts over gross outlays of funds).

^{1/} Food only (excludes alcoholic beverages). Not eeasonally adjusted. 2/ Excludes donations & home production. 3/ Excludes donations, child nutrition subsidies. & meals furnished to employees, patients, & inmates. P = preliminary.

NOTE: This table differs from Personal Consumption Expenditures (PCE), table 2, for several reasons: (1) this series includes only food not alcoholic beverages & pet food which are included in PCE; (2) this series is not seasonally adjusted, whereas PCE is seasonally adjusted at annual rates; (3) this series reports sales only, but PCE includes food produced & consumed on farms & food furnished to employees; (4) this series includes all sales of meals & snacks. PCE includes only purchases using personal funds, excluding business travel & entertainment. For a more complete discussion of the differences, see "Developing an Integrated Information System for the Food Sector. "Agr.-Econ. Rpt. No. 575, Aug 1987.

1/ in pounds, retail weight unless otherwise stated. Consumption normally represents the residual after exports, nonfood use, & ending stocks are subtracted from the sum of beginning stocks, domestic production, & imports. Data on a calendar year basis except fresh citrus truits, apples, grapes, dried fruit, peanuts, & rice, which are on a crop-year basis. 2/ Preliminary. 3/ Boneless, trimmed weight 4/ Beef, veal pork, lamb & mutton. 5/ Chicken & turkey, &/ Natural equivalent of cheese & cheese products. Total product weight is greater than natural equivalent because processed cheese & cheese food are made from natural cheese & other daity products. Includes miscellaneous cheese not shown expansitely. 7/ Plain & flavored. &/ Plain & havored & buttermilk. 9/ Heavy cream, light cream, & half & half. 10/ includes confectioner's tats & other edible fats not shown expansitely, 11/ Total may not edd due to rounding. 12/ Farm weight. Figures reflect par capita utilization rather than consumption due to lack of stocks data. 13/ Apples, apricots, avocados, bananas, cherries, cranberries, figs, grapes, kiwifruit, mengos, nectarines offices, papayas, peaches, peasimona, pineapples, plums, & pomegranates, 14/ includes grapefruit, lemons, limes, tangelos, & tangerines, 15/ Single-strength basis, 16/ On-cob basis, 17/ includes artichokes, garlic, & eggplant. 18/ Fresh & processed, 19/ White, whole wheat, semblina, & durum flour. 20/ Excludes fresh pasta artichokes, garlic, & eggplant. 18/ Fresh & processed. 19/ White, whole wheat, semblina, & durum flour. 20/ Excludes fresh pasta products. & canned & flozen products made with tresh pasta. 21/ Dry weight equivalent, includes refined (cane & beet) sugar, corn sweeteners, edible syrups, & honey. 22/ Per capita for U.S. total population, 21 years & over, 23/ Chocolate liquor is what remains after cocoa beans have been roasted & hulled; it is sometimes called ground or bitter chocolate. — = not available.

A USDA/ERS BRIEFING BOOKLET

THE 1990 FARM ACT **AND THE 1990 BUDGET** RECONCILIATION ACT

How U.S. Farm Policy Mechanisms Will Work Under New Legislation

This new 40-page booklet, explaining new farm legislation, has just been released by the Economic Research Service of the U.S. Department of Agriculture. This booklet explains the main features of the new 5-year farm law in easy-to-follow pages of illustrative material. These "verbal graphics" act as a self-programmed instruction method, as the reader easily proceeds from one point to another. The booklet works in the same general way as an informal briefing which makes its points step-by-step with overhead transparencies.

The booklet begins with an overview of the goals which motivated changes in farm legislation, accompanied by the most important mechanisms that support them.

Main goals Basic Mechanisms Reduce the Federal deficit Reduce payment acres

Improve agricultural competitiveness -> Permit planting flexibility; Maintain market-oriented loan rates

Enhance the environment Implement Agricultural Resources Conservation Program

The booklet then proceeds with definitions and illustrations of basic mechanisms of farm policy for the next 5 years:

- Target Price
- Loan Rates
 Deficiency Payments
- Crop Acreage Base
- Zero-92
- Farmer-Owned Reserve

Payment Limitation

To order your copy of this timely publication, just dial 1-800-999-6779. Call toll free in the United States and Canada. Other areas, dial 301-725-7937. Ask for "The 1990 Farm Act and the 1990 Budget Reconciliation Act," order # MP-1489.

Cost per copy is \$8.00. Non-U.S. addresses (including Canada), please add 25 percent. Charge your purchase to your VISA or MasterCard, or we can bill you. Or send a check or purchase order, made payable to ERS-NASS, to: ERS-NASS

P.O. Box 1608 Rockville, MD 20849-1608

We'll fill your order by first-class mail. We offer a 25-percent discount when you order 25 or more copies to one address.
